The remedy for most of the cases falling within groups two, three and four, is suggested by coöperation with our child-placing agencies. If a child must be cared for outside of his home, the next best arrangement is a foster home, wisely chosen as to the needs of the individual child and carefully supervised. As this means of disposal necessitates an outlay of considerable effort and money, the prognoses of the various cases must be carefully considered, and regarded as investments. Are we reasonably sure of getting lasting results? Is the child teachable? Can the home situation be bettered so that all the good work may not be lost when the patient returns home? A good many cases under the fourth heading fail to measure up to these standards, because of poor stock, incapable of being taught or helped. There is really little hope of doing any lasting good for these—they are social incurables. A child-placing agency is quite justified in refusing to accept the burden of a child whose heart is hopelessly crippled, or whose family is socially incurable. If, for humane reasons, action must be taken and the family are willing to give the child up, guardianship should be obtained for a number of years, and the burden should be one for public rather than for private support.

Group five has caused us some of our hardest struggles, and some of our most bitter disappointments. It seems nothing short of criminal that neglect on the part of the parents may spoil a child's every chance for efficient manhood or womanhood. Yet this happens in a good many cases and we are usually powerless to prevent it.

A young Syrian boy of ten years came into our care in 1912. His father, a man of intelligence and thrift, had died a year before. His mother was ignorant, shiftless and powerless to control her five children, who were rapidly becoming delinquent. A pension from the city and state enabled her to keep her home within the congested part of the city, from which she refused to move.

The boy, a bright, promising and responsive little fellow, recovered from his attack of acute rheumatic fever and acute endocarditis but was left a mitral lesion. After six months of care and study at the convalescent home it was thought economic and advisable to place him in a foster home until he should become trained in how to care for himself, and until his heart could get back as much of its original

efficiency as possible. By the fall of 1914 he had improved remarkably in every way and with the exception of violent exercise he was allowed practically all the activities of a normal boy. His foster parents and teachers spoke highly of his promising ability. However, his approaching earning capacity appealed to his mother. In spite of all the persuasion that could be brought to bear and notwithstanding repeated assurances on our part that the child had been made and kept well only by the most careful attention to his hygiene and exercise, she took him to her crowded and unsanitary home.

In four weeks he suffered an attack of rheumatic fever with new endocarditis. His mother took him to a physician who, having seen him once in his office, said he would do well at home but must be flat on his back for six months! The physician later told the social worker, who inquired concerning the boy, that in his opinion the heart was hopelessly crippled; that he would never amount to anything and that the mother's rights should be respected!

Which medical opinion should have more weight? That of the doctor who had watched the boy carefully for two years and knew the capacity of his heart, or that of the doctor who had seen him only once? And which plan respected the mother's "rights" more, the one which was made to watch her boy and help him to grow to self-supporting manhood, or the one which allowed her in her foolish ignorance to spoil the boy's future usefulness?

The Massachusetts law regarding the physical neglect of children is useless in such cases. The term "neglect" may be interpreted to mean neglected medical treatment, which in turn may be interpreted broadly. But the court is powerless to act against parents who refuse medical treatment for their children, if any physician will appear in court and testify that the treatment is not necessary.

The lesson to be drawn from this and similar cases is, that it is much safer to procure guardianship at the outset of such cases as need a long period of treatment away from home on account of neglect.

In considering children with cardiac disease, the school problem is a great one. There is so much loss of time that they fall behind children of their age and are seriously handicapped. A comprehensive scheme provides for teaching these children in their homes and for close co-operation with teachers and school nurses as soon as they are able to return to school. Teachers are often glad to advise the visitor about home lessons. The problem would be much simpler if more of the schools had elevators. Still some plan can usually be made with the help of interested and resourceful teachers. When there is no class of the required grade on the first floor, it is sometimes possible to transfer a child to another building, where a longer walk but no stair climbing may be involved.

In Boston there are ungraded classes which are small and which provide more individual teaching than is possible in grades of usual size. Such a class on the ground floor is a splendid

place for a child who has lost a great deal of time because of heart disease. Children may attend for a half day only, when just returning to school after illness; they may be excused from exercises; they may have special supervision at recess and they may pass in and out of school before or after the files.

Instruction and amusements for the child who is acutely ill, must be of the simplest kind and must be carefully supervised, to prevent them from making the patient tired or nervous. As much harm can be done, however, by taking all occupation away from a child as by allowing him to overdo. Oftentimes simple hand work is of great benefit to choreic patients. I have seen children with obstinate cases of chorea, particularly of the hands improve and recover when knitting was given them. Scrapbook making, simple weaving, knitting and bead work, modeling with plasticine, painting and coloring of pictures, cutting out of paper dolls and doll house furniture are all easily done in bed. An attempt should be made to provide work which has a purpose, as it interests the patient longer than a mere toy. The game "Meccano" is very popular with older children, also we always have a lending library on hand for their use.

The child and his parents should early be taught the possibility of permanent handicap and should be made to feel that the very best possible education is going to be of untold advantage to him. Unskilled work usually involves physical strain, and is consequently a great danger, which should not be risked. Every child suffering with heart trouble should be given the benefit of vocational training.

It is our policy to "graduate" children at 13 or 14 years of age to the adult medical clinics, where they are supervised medically by a special physician and socially by the social worker in that clinic. This social worker helps to make it possible for the child to attend high school or a trade school and sees that he learns some occupation which he can safely undertake.

With such a program extensively carried out we should have fewer misfits in industry and fewer cardiac patients in our wards who do not know how to support themselves except by unskilled manual labor.

I do not think that the logical development of care for children with heart disease is along institutional lines. An institution where these children can be cared for and taught does not seem practical or necessary. Those who need institutional care for a long period of time, namely, those whose hearts have received such damage as to make them permanent invalids, are comparatively few in number. There is little to be done for them except to keep them as happy and contented as possible during their lifetime, and for them there should be provision in homes for incurables.

Emphasis should be placed where preventive work is possible, namely, on the physically and socially hopeful cases. These far outnumber

those who are unhelpable. A long time spent in an institution does not teach children with heart disease how to adapt themselves and their limitations to normal family or community life. They become a class apart like the blind and deaf. Constant association with others disabled like themselves tends to make them neurasthenic. This tendency has always to be constantly guarded against when working with children where so much emphasis must be placed on their physical disability along certain lines.

In closing I should like to suggest the outline of a program for the efficient care of children with heart disease.

1. Adequate medical treatment.
 - a. Ward treatment when necessary.
 - b. Out-patient treatment, patients to be seen always by the same physician.
2. Adequate social treatment based upon medical treatment and following along closely with it. This should include:
 - a. Consideration of the home environment, both physical and mental.
 - b. Consideration of the school environment both physical and mental.
 - c. Consideration of suitable recreation and occupation.
3. Supervision over a long period of time.
4. Vocational guidance and training.

TONSILLECTOMY AS A THERAPEUTIC MEASURE IN THE TREATMENT OF CHOREA AND ENDOCARDITIS.

BY J. HERBERT YOUNG, M.D., NEWTON, MASS.,

Physician to Children's Medical Out-Patient Department, Massachusetts General Hospital.

[From the Children's Medical Department, Massachusetts General Hospital.]

SINCE July, 1911, an intensive study of endocarditis in children has been carried on in the Children's Medical Department of the Massachusetts General Hospital. These patients have been under observation by the same physicians for varying lengths of time, thus allowing each physician to follow out consistently different methods of treatment. The social condition of each patient has been investigated and followed by a special worker in the social service department, whose intimate knowledge of the patient and his home conditions has been of inestimable value to the physician in prescribing and carrying out treatment.

Before the work had gone on many months it became apparent that a place must be provided for patients not sick enough to occupy a bed in a general hospital but still too sick to receive adequate treatment at home. For this purpose a

Convalescent Home of 10 beds was established, where these children could have absolute rest in bed for weeks or months, and where, when able to be up, their activities could be carefully regulated and controlled. The Convalescent Home was in operation from December, 1911, to March, 1914, and in that time 54 patients between the ages of 5 and 12 years were treated, with an average of 107 days per patient. These patients were referred from both the out-patient department and wards. All patients had an acute or chronic endocarditis or were cases of chorea, arthritis or tonsillitis in which endocarditis was suspected. Of the 54 cases, 21 had a tonsillectomy performed either before they first came under observation, or while under observation, and it is with the end results in these cases that this paper deals. These patients, with few exceptions, have reported regularly to the out-patient department since their discharge from the convalescent home.

In all but three of the 21 cases, tonsillectomy was done in the out-patient department of the Massachusetts General Hospital. In two cases, operated upon outside the hospital, the condition of the tonsils before operation is not known; in the other case the tonsils were described as "considerably enlarged." In 11 cases the tonsils were described as "large," "enlarged," "very prominent" or "prominent and ragged." In 4 cases as "slightly+," "moderate," "slightly enlarged and inflamed" or "moderately enlarged." In one "buried," in one "not visible" and in one "small."

Of the 21 cases 6 gave a history of previous tonsillitis. Five patients gave a history of previous arthritis; since tonsillectomy 3 patients have been free from arthritis, while 2 patients have had subsequent attacks, one 2 months, the other 27 months, after operation.

A history of chorea previous to operation was given in 9 cases. After the removal of the tonsils 8 of these cases had from one to four attacks of chorea. There were 4 patients who have had from one to four attacks of chorea since the removal of the tonsils with no history of previous attacks. The one patient who has been free from chorea since the removal of the tonsils is a boy, aged, when first seen in March, 1913, seven years. At this time he had chorea with a heart of normal size, but with a loud functional murmur. He was in the ward one week and home in bed 11 weeks. From June 6, 1913, to October 16, 1913, he was in the convalescent home, and while there showed no sign of chorea. Examination of the heart on discharge showed the apex beat in the fourth space in the nipple line, the left border of dullness corresponding, 6.5 cm. to the left of the median line. Right border 2.5 cm. to the right of the median line. There was a rough systolic murmur at the pulmonic area, diminishing in intensity toward the apex but audible there, not heard in the axilla. On December 31, 1913, the tonsils and adenoids were removed, at which time there was slight chorea.

On April 25, 1914, a faint apical systolic murmur was heard for the first time. On November 21, 1914, the record states there is "probably a very slight mitral leak," with no demonstrable hypertrophy. Up to the present time the boy has had no more chorea, is under no restraint and is free from symptoms.

Of the 21 cases, 12 cases were known to have a definite endocarditis before tonsillectomy. One patient had an acute arthritis with a questionable endocarditis when first seen, no history of chorea or tonsillitis. Six weeks before operation the heart was recorded as normal and has remained so. There have been no subsequent attacks of arthritis nor chorea. Of the remaining 8 cases it is impossible to positively prove the absence of endocarditis before operation, since it was not at that time, as now, the routine to examine, in the Children's Department, the heart and lungs of each patient the morning of operation.

At the present time 17 cases show a chronic endocarditis, and of these 12 were known to have had endocarditis before operation. Three patients have had a fresh endocarditis or an acute exacerbation of a chronic endocarditis since operation, and in two patients the diagnosis is probable but not certain. Of these five cases, endocarditis was definitely known to be present before operation in two. One known and one suspected case of acute endocarditis now have normal hearts. Since operation one patient has been discharged from the ward with the diagnosis of subacute endocarditis.

It has generally been assumed that tonsillec-

tomy, even if it offered no benefit, could do no harm, excepting the immediate danger of the operation. This statement is questioned by two cases in this series. One patient had chorea 12 months before operation, with no history of arthritis, tonsillitis or endocarditis. Two weeks after the operation she had her second attack of chorea, complicated by an endocarditis, probably acute. The other case gave no history of chorea, arthritis or tonsillitis before operation. The heart was examined three weeks before operation and found normal. Five days after operation the patient had chorea and an acute endocarditis.

The present condition of 3 patients is unknown. Of the remaining 18 patients, 12 are well, 2 have no endocarditis, 10 still have an endocardial murmur, and, with one exception, show slight cardiac hypertrophy. These patients are well in so far as they have no symptoms and enjoy all the normal activities of childhood without restraint. The physical activities of 4 patients are still more or less restrained. One patient is now having her third attack of chorea. Another patient, when last seen in November, 1914, was having her fourth attack of chorea and up to this time has had no endocarditis.

Definite conclusions cannot be drawn from so few cases. The occurrence of chorea after tonsillectomy in 12 out of 21 cases strongly suggests, however, that removal of the tonsils does not offer the protection against chorea, and the always present possibility of endocarditis, that many have heretofore believed.

Medical Progress.

REPORT ON DERMATOLOGY.

By JOHN T. BOWEN, M.D., BOSTON.

FATAL POISONING FROM RESORCIN APPLICATIONS.

FEW cases of severe constitutional poisoning from the outward application of resorcin are on record. In one of the reported cases the patient was a man of 29, who had been treated with a 50% resorcin paste for a very extensive lupus vulgaris; another, a boy of 19, had rubbed in a 15% resorcin ointment over a large surface of the skin.

Boeck's¹ case was that of a poorly nourished boy of 16, who had been affected by a very extensive lupus vulgaris from his third year. The whole of the left lower extremity, and the greater part of the left upper extremity was covered with numerous closely aggregated lupus nodules. He was treated at first by the Finsen light, with experimental applications of a 27% resorcin paste on the left arm, which caused a certain amount of pain and discomfort. Later a 25% resorcin paste was applied to the greater part of the left calf, where the skin was covered with intact epithelium. The application was made at about 10.30. He began to be restless half an hour after the application had been made, and to complain of severe pain, but gradually became quiet. He was found, 1½ hours after the application, unconscious, cyanotic, with spasmodic twitching of the right arm, pulse 120, temperature 37.8°. Shortly afterward he developed convulsive movements of the face, right arm and leg, and later the left side of the body. The pulse became 150, the respiration frequent, ceasing at times for a minute. The pupils were at first much dilated, later contracted. The convulsive attack lasted the whole afternoon, ceasing towards night, and was followed by death in the early evening. At the autopsy the chief finding was a very pronounced edema of the brain. There was a widespread glandular tuberculosis, and tubercular foci in the apices of both lungs.

There could be no question that death was caused by poisoning from resorcin. The symptoms of such poisoning are very characteristic, consisting of quickly appearing restlessness and wandering, followed by cyanosis, coma, and severe convulsions. Ordinarily the patient recovers quickly, awaking almost perfectly well.

The result in this case was most unexpected, as Boeck had used resorcin in cases of lupus during a good many years in even higher percentages than in the present case. In this case, to be sure, somewhat larger surfaces than usual were treated, but these surfaces were everywhere covered with a thick, intact, horny layer, which therefore was not able to prevent the poisoning. This fact was recorded also by Andeer, who found by his experiments that, although resorcin

intoxication did not occur in the presence of a completely sound skin, an intact epidermis afforded no security against poisoning in the presence of an underlying morbidly affected corium. Resorcin is a dioxybenzol, and in any case the substances that are formed by its contact with the skin must be of very transient nature, as symptoms of poisoning may occur a quarter of an hour after its application.

On account of this case Boeck advises that in the future resorcin be not employed in large doses over considerable surfaces. In the treatment of lupus vulgaris he considers that we have even better and more effective chemical agents in pyrogallol and salicylic acid. He had previously employed resorcin in such cases for the reason that he considered it the mildest application. He considers resorcin more effective against lupus of the mucous membranes, when not extensive, than any other chemical or physical agent. In lupus of the nasal cavity he uses a resorcin paste, made up of equal parts of resorcin, talcum and vaseline, applied twice daily for a week.

TUBERCULOSIS TYPES.

Lipschütz², in a study of the recognition and significance of the several types of tubercle bacilli in the clinically different forms of cutaneous tuberculosis, comes to the following conclusions:—

1. The different varieties of tubercle bacilli,—human, bovine, and gallinaceous, occur in man as the cause of the different varieties of tuberculosis of the skin.

2. Mutual infection between men and animals is possible; hence prophylaxis should deal with fighting not only human, but bovine and gallinaceous tuberculosis.

3. In by far the greater number of all hitherto studied cases of cutaneous tuberculosis, the human type has been recognized as the cause.

4. The bovine type occurs regularly in tuberculosis verrucosa cutis (Riehl-Paltauf), which is therefore to be defined as a true inoculation-tuberculosis with bovine bacilli. This inoculation infection remains almost always localized; it progresses in very exceptional cases to glandular swellings and lymphangitis.

5. While verruca necrogenica ("anatomical wart") is probably, contrary to tuberculosis verrucosa, an inoculation-tuberculosis with human bacilli, lupus vulgaris must be regarded as caused both by the human and bovine type, much more frequently by the former. Contrary to the belief of older writers, lupus vulgaris is a bovine skin tuberculosis in only a small percentage of all cases.

6. The significance of the gallinaceous type in the genesis of rare forms of cutaneous tuberculosis is not to be underestimated. In case of failure of experimental inoculations in guinea pigs, the diagnosis of tuberculosis should not be

at once rejected, but the possibility of a gallinaceous tuberculosis be suspected, and inoculation experiments attempted on fowls.

7. The following characteristics of gallinaceous tuberculosis of man may be enumerated: the occurrence of bacilli in very great numbers, their occurrence almost exclusively within cells, and tissue changes which differ markedly both clinically and microscopically from the typical appearances of ordinary tuberculosis.

TREATMENT OF X-RAY BURNS.

Bogrow³ of the dermatological clinic of Moscow remarks that dermatitis from x-rays is comparatively seldom seen nowadays, since our knowledge of their properties has caused the introduction of various precautionary measures. The cases that are on record attest the obstinacy that these lesions offer to any of the conservative measures of healing. In fact, the treatment of these burns is one of the most thankless tasks of the dermatologist, as the degenerative conditions produced in the tissues by the rays can never be repaired.

The therapeutic measures indicated in reactions from the x-rays depend on the intensity of this reaction. In case of a simple Roentgen erythema, cold compresses of lead water may be sufficient, or warm boracic acid applications, soothing ointments and powders. Cocaine, or thoform, etc., have been said to cause increased inflammation and necrosis of the tissues. Injections of morphia are the best means of relief in the case of intense pain. The ulcers caused by the rays are most resistant to treatment, on account of the deep vessel changes and the danger of necrosis of the bone, and the resulting scars often break down.

According to Hagar all methods of treating x-ray burns may be divided into conservative and surgical. In the first category belong warm compresses with substances that have an antiseptic action, such as sublimate, lead water, peroxide of hydrogen, etc. Kolleker obtained good results with a one per cent. solution of creolin. For hastening the process of granulations and epithelial regeneration the ointment of red oxide of mercury, a ten per cent. carbolic oil, an eight per cent. ointment of Scharlach R, have been recommended. Of physical methods, compression by bandages and by Bier's procedure, exposure to electric lamps and radiotherapy have been advised; also, exposure to the sun after treatment with eosin, the Finsen treatment, the galvano-cautery, and carbon dioxide snow. In only a small number of these cases, however, have these procedures proved of marked effect. Surgical intervention was indicated by attacks of pain and fever. In most instances radical operations, consisting of excision of the ulcerated portions, followed by a plastic, have been resorted to.

Roentgen ray cancer can almost always be removed by operative means. Pre-cancerous

keratoses are treated with liquid air, or carbon-dioxide snow. Some of the latter heal by application of nitric acid, or after acute infections.

Bogrow reports the following case treated by the Pfannenstill method. It was that of a woman of 58, who presented a large painful ulcer in the left hypochondrium, caused by the application of x-rays for internal treatment. After some preliminary trial of other forms of treatment, it was decided to resort to Pfannenstill's method. The principle of this is the generation of nascent iodine in the tissues, effected by the internal administration of iodide of sodium, combined with the local treatment of the affected portions with peroxide of hydrogen. The only contra-indication to this method is idiosyncrasy to iodine. In the case reported, the x-ray ulcer, that had shown no sign of healing for five months, began to "clean up" immediately after this method was employed, and to become covered with epidermis. This improvement was interrupted after four months by stopping the treatment, but on its resumption the ulcer was completely healed, with a simultaneous disappearance of the pain. The scar that had been previously hyperemic, became paler. The healing occupied seven months from the beginning of the treatment. Inasmuch as the time of healing of an x-ray ulcer is very long ordinarily, extending sometimes over a period of years, the result of treatment in this case must be considered as particularly favorable.

WAR APHORISMS OF A DERMATOLOGIST.

Unna has been sending a series of short articles with the above heading to the attenuated *Berliner Klinische Wochenschrift*. We quote the topics touched on in the issues of this current year, numbered 9, 12, 14, and 18.

1. *Furuncle*. Field surgeons in the present war have told him that the old way of treating boils, by means of a crucial incision, still obtains. As bacteriology has taught that furuncles are due to the penetration of cocci into the hair follicles, it is essential that the lesion be incised in the centre by a perpendicular stab. He recommends his "mikrobrenner" as the best instrument to use, next the finest point of the Paquelin cautery, or a sharply pointed stout needle that has been passed through the flame of a spirit lamp. By this procedure pain and feeling of tension cease at once, and the part should be painless on pressure. The advantages of this method over a crucial incision are that the foci of cocci are disinfected *in situ*, that it destroys these alone and not the contiguous skin, that the pain is instantly relieved and that it leaves no scar.

2. *Furunculosis*. In the field, where baths, soap, and most of the approved methods of treating furunculosis are impossible, the methodical cauterization of all the individual furuncles is the best treatment. When this is not practicable, Unna recommends a paste of kaolin, ich-

thyl and glycerine, in the proportion of 20, 10, and 5, covered by an impermeable dressing. Failing these means, or when there is much irritation, a paste of sulphur, zinc, carbonate of calcium and glycerine may be substituted. A soft mercurial plaster may also be improvised and used with good effect.

3. *Axillary Abscesses.* Surgeons in the field often meet with furuncular inflammations in the axillae in strong healthy subjects, occurring, especially after prolonged sweating. They differ from furuncles in so marked a degree clinically that other organisms than those that cause furuncles must be active. They begin as round nodules in the corium, which increase slowly, accompanied by much inflammation and tension, and become finally soft, fluctuating abscesses which evacuate purulent matter, but no necrotic plugs, as in furuncle, and do not heal spontaneously, like the latter. They recur readily, during months and years, with remissions in the winter, but always locally, in the axillae. They never cause erysipelas, sepsis, or metastatic abscesses. The treatment is the same as that of furuncles.

4. *Weeping Eczema.* Moist affections of the skin, if of any extent, render the subject unfit for service, especially if the customary bandaging is employed. Better are the absorbent drying pastes, of which a good one for the field is composed of sulphur 10, carbonate of calcium 10, zinc oxide ointment 80. This should be employed frequently, but in small quantity. Believing as he does, that eczema is caused by cocci, Unna declares that borie acid, and antiseptic applications in general are powerless against this affection. Drying and reducing agents, such as sulphur, zinc oxide and chalk, are indicated.

5. *Dry Eczema.* For the yellowish, greasy, scaling spots of seborrhoeic eczema of breast, abdomen, neck and arms, the above zinc-sulphur-chalk-paste is indicated. Callous eczemas require reducing agents. Hebra's ointment is valuable, and salicylic acid and tar are useful adjuvants. Ichthyol, resorcin, and pyrogallol cannot usually be supplied by the field apothecary.

6. *Psoriasis.* A psoriasis, even if quite extensive, does not, in this war, debar from service, as it does not affect the general health, does not itch as a rule, and is serious only when the hands and head are affected. Treatment in the field must naturally be limited to alleviating the worst symptoms and holding the affection in check. Chrysarobin may be obtained, but it must be used cautiously to avoid risk of overstimulation, and consequently should not be used in ointment form. Chrysarobin 2, ol. terebinth 2, collodium 16, may be painted over the whole body with the exception of the head. The oil of turpentine increases the oxidation effect of the chrysarobin on the skin. A white precipitate and sulphur ointment may be used on the face.

7. *Scabies.* In the numerous cases in which the scabies is complicated by an eczema the above mentioned zinc-sulphur-chalk paste may be used

for the inflammation, to which is added from 2-5 per cent. of balsam of Peru, against the scabies. This salve is rubbed two or three times daily into all the infected places till the affection is healed. Pure balsam of Peru is not advisable on account of the high cost, the pain it causes, and its impotence against eczema and furunculosis. For pure cases of scabies Sherwell's sulphur cure is advised, the patient himself rubbing pure powdered sulphur into the places that itch, at any time, but especially during the night. The patient is ordered to rub in sulphur instead of scratching. Two or three days usually suffice for a cure.

8. *Pyodermia. Impetigo Bockhart.* Unna emphasizes the difficulty that surgeons at the front experience in overcoming this class of affections. These affections, the impetigo contagiosa of Tilbury Fox and the impetigo of Bockhart are to be separated from the class of impetiginous eczemas. All the impetigos are caused by the same yellow and white pus cocci or by streptococci. But Bockhart's impetigo is a much more serious affection than impetigo contagiosa as it contains the real pus cocci and may lead to sepsis, and to generalized cases of pyodermia. Bockhart's impetigo, as opposed to impetigo contagiosa, is a rare occurrence in times of peace. In war, it is much more common, and is fostered by the unfavorable conditions. Prophylaxis is of the utmost importance. Boils and panaritium must be carefully treated, as they may infect the adjacent hair follicles. The treatment is the same that has been enumerated above. Thorough soap and water washing of the whole body must be employed when the patient is in a hospital, or when it is possible.

9. *Erysipelas.* Unna considers ichthyol, which was introduced by him in internal medicine and dermatology first in 1884, and in the following year recommended for erysipelas by Nussbaum, as still the only sure external means of treating this affection, but this cannot always be obtained at the front. The internal use of ammonia is recommended in cases in which it is impossible to procure ichthyol, in the following prescription:—

Ammon. Carbonici5.0
Liq. Ammon. anisati5.0
Aquae ad200.0
Syr. simpl20.0

Sig. A tablespoonful every hour or two.

MODERN DIAGNOSTIC METHODS IN SYPHILIS.

Fordyce* of New York, whose opportunities for observation are unsurpassed, read a paper with the above title at a meeting of the New York Academy of Medicine, the summary of which is here copied. It may be recommended to all who have to do with syphilis.

"The Wassermann reaction is one of the most important symptoms of syphilis, the interpretation of which can come only from experience—

prolonged experience and careful comparison of laboratory results with clinical observation."

Fordyce emphasizes the importance of careful clinical training in recognizing the various stages of the disease, and declares that unless the available facilities for laboratory examinations are trustworthy, it is better to be guided by clinical experience alone than to be misled by improperly made or interpreted laboratory tests. "There is great necessity for the standardization of the technic. All modifications introduced up to the present time, have proved inferior to the original method and cannot therefore supplant it."

"A positive Wassermann is pathognomonic of a luetic infection, with the following reservations: Partial or transient complement fixation is sometimes seen in leprosy, yaws, and cachectic states, but it is obvious that, with the exception of leprosy, which is the only disease to present any perplexity in this climate, the clinical diagnosis would offer no difficulty. In the cases of leprosy which have come under my observation the reaction does not occur uniformly, some cases giving the reaction at one time and not at another, or negative and indeterminate with one antigen, while inhibition may be complete with another. An indeterminate or weakly positive reaction is of value as indication for treatment, but is of little importance for diagnosis unless as a concomitant of other symptoms, when it may in many cases be brought out by a provocative injection of salvarsan."

"In interpreting negative reactions one must bear in mind that they may occur with limited tertiary affections, in old infections with the disease limited to the central nervous system, and in women with repeated abortions, or in syphilitic children in whom the infection is remote or has been treated. Alcohol taken prior to the test will sometimes prevent the fixation of complement. Individuals who are addicted to its use should, therefore, abstain for several days before the blood is to be examined."

"In the primary period of syphilis, every effort should be made to establish a positive diagnosis. If the dark field examination is negative and the clinical picture doubtful, repeated Wassermann examinations should be made, as they are usually positive before the outbreak of the secondary rash."

"The Wassermann is positive in the secondary stage in 100% of cases, and is of value in differentiating between early syphilitic eruptions and dermatological affections which simulate them. In the latent stage it is a valuable guide to the effect of treatment. It is impossible at the moment to give the percentage of cases which will remain refractory to treatment and to say to what extent we are justified in continuing to treat such patients."

"Untreated tertiary cases with manifest symptoms give a positive reaction in from 95 to 100% of cases. The test is here of diagnostic importance in differentiating luetic affections from tumors or other surgical conditions, and supplies the

etiology in cases of repeated abortions where no history of syphilis is obtainable."

"The provocative reaction is of great aid in cases with suspicious lesions and a negative reaction. It should be applied in all treated cases where the reaction has been negative for a period of a year or more, to determine if a cure has taken place. If it becomes positive, there is an indication for renewal of treatment, and if it remains negative, the provocative should be repeated within a year, following the policy of Genmerich. All patients with symptoms pointing to involvement of the central nervous system should have a lumbar puncture, as well as the latent cases with persistent positive reactions, to determine if there is a latent process in the cerebrospinal system. The puncture is of value, not only in making a differential diagnosis between various neurological diseases, but as an index of the activity of a syphilitic process and a control of the effect of treatment."

"The findings in syphilis of the nervous system are as follows: In tabes the reaction of the blood is positive in 60 to 70%. In the spinal fluid, Phase I and lymphocytosis are usually marked in about 100% of well developed cases with active manifestations. The Wassermann is positive with larger amounts of fluid, and about 20% give a reaction with 0.2 c.c. or less. In the early forms of the root-type, the serological picture may be practically negative; whether these cases will give positive findings later on, only further observation and time can tell. In the degenerative forms, where all activity has subsided, the results are negative."

"In tabo-paresis and paresis the picture is about the same, *i.e.* a positive reaction in the blood in about 100% of the cases; in the fluid a positive Phase I and a variable lymphocytosis with a positive Wassermann in larger amounts in 100%, and with 0.2 or less in about 95%."

"In cerebro-spinal lues the reaction in the blood is positive in 70 to 80%, Phase I is usually positive, pleocytosis is variable, complement fixation is positive in large amounts; a smaller percentage fixing with 0.2."

"In cerebrospinal arteritis the blood may or may not give a positive reaction. The findings in the fluid may all be negative, excepting the globulin reaction, unless there is an accompanying meningitis."

THE ALOPECIA OF HYPOTHYREOSIS.

Montgomery⁵ of San Francisco reports an interesting case that he considers to have been of this etiology. He remarks that a diminution or absence of the secretion of the thyroid gland is known to cause the following changes in the skin: Myxedema, roughness and dryness of the skin; yellow complexion with a rather circumscribed redness of the cheeks, called the "malar flush"; dry seborrheic coating of the scalp, constituting at times a thick crust; dryness, lack of lustre and wiriness and defluvium of the hair;

acroparesthesias; chilly feelings of the cutaneous surface; dystrophies of the nails.

The case in question was that of a man of 41, of sedentary habits, whose hair had been thinning at the vertex and retreating from the forehead for two years before he came under observation. The scalp was covered with greasy, tightly adherent scales. It was a type of the senile seborrhoeic variety, as it occurs in the male.

The face of the patient was considered important, being fat, heavy, and expressionless, with a dull thick skin of a lemon-yellow color, a red nose, a flush over the malar prominences, blue ears and pallid eyes. The lips were heavy, voice husky. There was in winter a pruritus of the thighs and legs which became purpuric on scratching. The gums were swollen and the teeth loosening. The thyroid gland could not be demonstrated.

He was put on a careful diet and given five grains of thyroid extract a day, under which regimen he improved rapidly. Eight months later the hair was growing rapidly, there being a new growth in some places where the fall had been complete, as at the frontal margin of the scalp. The nose became less red, and the condition of the gums improved. He began, however, to lose in weight, so the thyroid was cut down to one and a quarter grains. He then regained his weight, his health continuing to be good, and his hair, gums and teeth to maintain their improvement.

Although myxedema, one of the most characteristic symptoms of hypothyroidism, was lacking in this case, Montgomery considers that the other symptoms were sufficient to place it in this class. The loss of weight, which was arrested on decreasing the dose of thyroid extract, is considered as additional evidence in this regard. It has been claimed that a moderate degree of thyroid inadequacy is not infrequent, and that people in middle life are often benefited by thyroid treatment, both as regards their general health, removing excessive corpulence, and promoting the growth of hair; and that these good results may be due to the actual replacement of a function that is being insufficiently discharged. This is evidently what occurred in the present case. The faulty oxygenating processes were re-established by the thyroid extract so that the digestive and blood-making functions were stimulated. The writer asserts that he had never before seen anything like the condition of the gums shown by this patient, but as it improved on taking the thyroid extract, he considers that it may legitimately be regarded as one of the phenomena of hypothyreosis.

"The Mechanism of Anaphylaxis and Anaphylatoxin Production." By F. G. Novy, Ann Arbor, Mich.

26

"The Relationship of Chronic Protein Intoxication in Animals to Anaphylaxis." By WARFIELD T. LONGCOPE, New York, N. Y.

In the use of foreign proteins for anaphylaxis investigations certain necrotic lesions have been noted in the liver, the kidneys and the heart muscle of experimental animals. It was thought at first that these lesions were anaphylactic in origin and that they were due to a previous sensitization; but later it was shown that they occur after a single dose of protein. The question thus arose whether the lesions were due to anaphylactic shock or to direct toxic action of the protein.

In two series of animals, one group was given repeated doses of a single protein; a second group was given one dose of mixed proteins. All of the animals in the first group were found to have the lesions in the kidneys, liver and heart muscle. Those in the second group occasionally had them. Thus it was shown that there is no difference as regards the action of different foreign proteins. The question then arose as to the time of the occurrence of the lesions. Animals were found in eight days to have developed a local sensitization as expressed by a skin reaction which could be excited at the point of inoculation. In twenty days after a single large dose of horse serum, the necrotic changes may be found in the liver, kidneys and heart muscle and at the same time the skin reaction becomes more intense. These observations tend to show that the lesions alluded to are due to anaphylaxis and not to direct toxic action of the protein.

GROUP ON INTERNAL SECRETIONS.

27

"Studies on the Relation of Hypersusceptibility and Insusceptibility Induced in Guinea pigs by the Instillation of Horse Serum into the Nose." By HENRY SEWALL and CUTHBERT POWELL, Denver, Colo.

In work reported a year ago, there appeared certain peculiarities in the course of immunological reactions which were dependent upon giving the antigen through the nose. Further observations have been made in an effort to work out the idiosyncrasies of reactions produced by this channel. A priori it appears that these matters are expressions of nature and of physiology; but most experiments begin with a surgical operation of some sort—big or little. The nasal method had been adopted in order to avoid any operative procedure and because the amount of antigen absorbed by a natural route is more nearly parallel with nature.

The method adopted was this; a guinea pig was gently held on its back and 3 minims of horse serum dropped into its nose; the procedure was repeated at intervals varying from twelve hours to twenty five days. Forty-one guinea pigs were treated thus very other day for 6 days; in 16 days the instillation of a double dose into the nose was followed by the death of 21 of the pigs from anaphylactic shock; but 20 of the pigs lived; some of them had a hard time, some had no symptoms at all. When the serum instillation was repeated on the 24th day, still the pigs did not die and those that reacted did so less strongly; the reactions were still less marked after a third instillation, and still less after a fourth. What takes place as a result of these nasal instillations? It is taken for granted that absorption must take place; but how much of the horse serum is absorbed? Rosenau found that 1,000,001 cc. may sensitize a guinea pig; it may be assumed that about 0,000,001 cc. was absorbed in these pigs, at any rate after repeated instillations, each did something to the pigs. Two instillations were usually sufficient to produce a protective effect. Anderson found that immunization could not be induced in certain children by the use of subcutaneous injections of diphtheria toxin; others said it could be done with difficulty. But it may be done without harm by dropping undiluted diphtheria toxin into the nares of children. Two successive nasal instillations with an interval of 24 hours, and a third instillation in 6 days, in a few cases protected against very toxic doses injected.

These results are so different from generally accepted facts that they are presented for what they are worth. With these findings an explanation of the internal situation is necessary. Theoretically, the blood ought to be loaded with antibodies; but this is not found to be so. Dale, following Stulz, says that after repeated injections the uterus becomes very sensitive to antigens, but that in several instances in which the uterus came from desensitized animals, it was not sensitive. The writer found that a protected pig after 36 days nearly died from an injection of 1 cc. horse serum; but that two pigs kept 101 days did not react at all to 1 cc. serum. According to most authorities, these pigs should have been resensitized. His own idea is that the antigen produces some metabolic changes protective against subsequent doses. He found some pigs made refractory by injections of blood from protected pigs. Pigs born of mothers protected by the nasal method exhibited some resistance.

His conclusion is that resistance of the type dealt with in his work must be a tissue resistance; certainly the serum in his cases was very poor in antibodies in the ordinary sense.

"Pathological Changes Arising from Overaction of the Cervical Sympathetic." By WALTER B. CANNON and R. FRIZ, Boston, Mass.

The right phrenic nerve of cats was connected with the cervical sympathetic, the idea being that when fibres of the cervical sympathetic below the

superior cervical ganglion were thus connected with the phrenic they would be activated by a volley of impulses with every breath the animal drew. Several animals survived the operation and after a time developed curious symptoms. One of these is a great increase of the rapidity of the heart rate; in normal cats the pulse rate is 159, but in the treated cats the rate went to about 225. There is a characteristic looseness of the stools. There is some alopecia and a sort of scleroderma in places; there is evidence of pruritus. The cats become more irritable. There is a marked increase of metabolism; the calories lost per sq. meter per hour being in normal animals 31 and in treated animals from 58 to 72. The increased heat output is attended with loss of weight. There should be mentioned also an increase of the pupillary slit on the operated side and exophthalmos. These conditions progress until the animals go to pieces.

All these facts seem to indicate that the condition is due to over-activity of the thyroid gland produced by overstimulation of its innervation. A question to be answered is why do not the normal emotional stimuli cause the same symptoms under ordinary conditions, while in pathological states they do? The hypothesis is advanced that there is a protective threshold between the preganglionic and the post ganglionic fibres, but that when the threshold is worn down by repeated stimuli under adverse circumstances impulses are permitted to pass over and symptoms of hyperthyroidism arise.

GROUP ON NEPHRITIS.

30

"Studies in Nephritis." By HENRY A. CHRISTIAN, CHANNING FROTHINGHAM, JR., JAMES P. O'HARE, and ALLEN C. WOODS, Boston, Mass.

a. Test renal meals in relation to renal function.

The main conclusions derived from these studies were: (1) Of the two general methods that of von Monakow requires 10 days while that of Hedinger-Schleyer requires but three, and that as much can be learned from the three day method as can be learned from the longer. From the standpoint of economy both of patient's time and hospital care, the shorter method is to be preferred. (2) The results obtained from the two methods are similar but not quantitatively identical. For the Hedinger-Schleyer test there is no constant curve of secretion; evidences of abnormality consist of more or less fixation of concentration and of output. Fixation of N-output is the last evidence of abnormality to become appreciable.

b. Quantitative studies of the non-protein nitrogenous bodies of the blood.

Urea nitrogen constitutes the major portion of the increase in nitrogen retention and is proportionate to the non-protein nitrogen. The creatinin increase tends to be proportionate to the other forms, but the unknown forms constitute the greatest source of non-protein nitrogen.

The nitrogen in spinal fluid was also quantitated; there was no advantage in this method over blood estimates.

c. Diuresis in relation to diuretics.

Diuresis in response to diuretics is infrequent in hospital patients. The total intake and output of fluid was measured and only 15% of the cases showed any diuresis; diuresis being defined as any day's output in excess of 1600 cc. or in excess of

intake. When diuresis does occur it is most commonly seen in cardiac cases; in these digitalis and forced fluids are the most potent measures. Next in frequency of occurrence was diuresis induced in nephritis: one half of these responded; the most constant cause of diuresis was digitalis given in cardiac decompensation. The next group in point of frequency in which diuresis was observed was of diabetes and typhoid fever in which diuresis occurred after increased intake of fluid.

There were 10 cases of nephritis in which no diuresis could be induced with theocin, theobromine sodiosalicylate, sodium citrate or caffeine. This provokes skepticism as to the efficacy of these agents. There was no edema in these cases; therefore, no decompensation. In a small group with edema not due to decompensation (electrocardiograph), diuresis was very uncertain.

Diuretic drugs do produce diuresis but only in the right kind of cases. Diuresis may most often be induced in cases of combined renal and cardiac insufficiency; the best results follow theocin and digitalis, but in a few cases theobromine sodiosalicylate and digitalis act better than the first combination; why this is so is not known. Diuretics act best in cases with edema. If no edema is present diuretics do no good and may possibly do harm.

d. Functional tests in relation to anatomical changes in the kidney.

No more accurate anatomical diagnosis can be made with functional tests than without.

GROUP ON DIABETES.

34

"Long Fasting in Diabetes." By FREDERICK M. ALLEN, New York, N. Y.

Partial pancreatectomy with retention of the duct produces a satisfactory experimental diabetes, and animals prepared in this way can be studied advantageously. In mild experimental cases dietetic management suffices to keep the diabetes in abeyance. More severe cases quickly pass into an uncontrollable condition. If, in controlled cases, glycosuria is allowed to reappear, the animals quickly go down with destruction of the islands of Langerhans. Those kept sugar free stay lively and show no injury of the islands.

Patients at the Rockefeller Institute have been treated on the basis of these animal experiments. An initial fast of from 1 to 8 days will completely stop glycosuria in most cases. Fasting can be undertaken in very severe, weak cases without injury, but with benefit. There are some unsuccessful cases due to infections or other complications but these do not constitute contraindications to fasting.

If undesirable symptoms arise in the course of fasting, after an interval of careful dieting, fasting can be resumed and carried to success. If after fasting and becoming sugar free, as Joslin has shown, the sugar and acidosis are allowed to return, the last state of that man is worse than the first. But cautious underfeeding, with occasional fast days, will suffice to keep these patients in good condition. Well established is the advantage of keeping the patients below weight and of maintaining a low fat content in the diet, thus reversing the doctrine of Naunyn and others. Dietetic restrictions are renewed on the detection of ketonuria or increase of blood sugar. To insure freedom from ketonuria and glycosuria fat is necessarily withheld from diet.

The salient features of the paper are:

1. In diabetes an increase of weight or of metabolism throws increased strain on the pancreas and does harm.
2. Fasting suffices to render the blood and urine sugar free.
3. A suitable diet and interrelated fast days will keep diabetics sugar free.
4. The paper opposes the idea of keeping diabetics up to the highest level of weight and nutrition.
5. It opposes the doctrine that calories lost in the urine must be replaced in the diet. It is found that feeding fat for this purpose results in return of sugar.

The treatment suggested has been practically applied in many cases and is applicable by the practitioner everywhere.

The question remains whether diabetes is a progressive disease or a temporary metabolic error. If the first, the treatment will keep diabetics comfortable for a time; if the second, the treatment will keep them well.

35

"Present Day Treatment and Prognosis in Diabetes." By E. P. JOSLIN, Boston, Mass.

It is no exaggeration to say that the advance in the treatment of diabetes during the past year has been greater than any since Rollo. This is not by chance, but it follows work done in the laboratory and clinic, and is an eloquent answer to the critics of animal experimentation.

The advance in treatment has been such that we can now teach patients to observe themselves, examine their urine, to manage their dietary; because the physician can now control the situation absolutely. Thanks to Dr. Allen's work, we no longer nurse diabetics, we treat them.

Patients in the writer's practice have done better this year than ever before. Statistics are given.

Children do well under the fasting method; they obey readily and cooperate well. Complications disappear more rapidly than under any other management, especially carbuncles. A case of pregnancy with glycosuria to 6%, was carried successfully to term and was delivered by Caesarean section with recovery of mother and child. Operation of others sorts have been successfully carried out on diabetics. Cases of long duration and cases with severe acidosis do well under starvation management.

Some of the advantages of the method:

1. We have an attainable ideal toward which to work: to get patients sugar and acid free.

2. We are relieved of the machinations of quacks and the exploitation of drugs and patent foods.

3. The patient is relieved of the expense of long treatment and may go back to work.

Whether this treatment will influence those cases which under other regimes went on to sclerosis remains to be seen.

The following points are important in the technique of the fasting treatment: patients must be educated just as they have been in tuberculosis; they must not gain weight too fast; they must rest; they must remain under observation.

Query: Does coma represent a termination of diabetes? or, rather, is it not an avoidable accident?

36

"A Study of the Acidosis Occurring in the Nutritional Diseases of Infancy." By JOHN HOWLAND and W. McKIM MARRIOTT, Baltimore, Md.

37

"Mild Diabetes in Children." By DAVID RIESMAN, Philadelphia, Pa.

Fatal diabetes is at times an unavoidable accident in youth, but a mild diabetes occurs which may be satisfactorily treated.

A series of four cases is given in detail, all of which readily responded to dietetic treatment and all recovered.

The cases seem to belong to a well defined group called by Solomon, of Vienna, innocent diabetes of the young.

Glucose can no longer be recovered from the urine of the cases reported; this shows the high carbohydrate tolerance which can be regained. These cases of mild juvenile glycosuria may belong to the renal type.

1. There exists a mild type of glycosuria in juveniles.

2. There may be several cases in the same family.

3. The patients do not usually show the ordinary collateral symptoms of diabetes.

4. They are readily influenced by dietetic management.

5. They get well.

38

"Studies in Experimental Pancreatic Diabetes." By A. A. EPSTEIN and S. BAHR, New York, N. Y.

Only recently has it been possible to study glycosuria from the blood standpoint. By using the ferrie acid test of Allen and Benedict it is possible to get remarkably exact estimates in small quantities of blood.

The studies were made on depancreatized cats. Because of excessive thirst and large water intake, it was necessary to estimate changes in blood volume, which was done by a method of comparing the proportion of cells to plasma. Corrections of the blood sugar findings were made for blood volume fluctuations. The results of the corrections show a surprising difference from direct findings. Statistics were given.

All the cats showed a progressive rise in blood sugar, quite marked just before death. (This is not due to tissue decomposition because the rise begins while the animal is quite lively.) With the appearance of hyperglycaemia there is a diminution of

glycosuria. This is no doubt due to a renal insufficiency for sugar. For the reason that polyuria continues after the disappearance of sugar, failure of circulation is ruled out as a cause.

Experiments with pancreatectomy and double nephrectomy resulted in the production of a rise in hyperglycaemia, rapid in well nourished animals; in strayed cats this rise was late in appearing but when it appeared it was acute and reached the same level eventually as in the well fed cats.

GROUP ON SYMPTOMATIC TREATMENT.

40

"The Actual Value of Symptomatic Treatment." By JOSEPH L. MILLER, Chicago, Ill.

Symptomatic treatment is now generally neglected. Is this a step in progress or only a manifestation of the scientific spirit? Is symptomatic treatment valueless, or is the physician merely impatient of any treatment that does not bear scientific scrutiny? Should not the problem be approached by inquiries into whether the symptoms themselves do any harm? or whether they hinder recovery?

When applied to undesirable symptoms, the use of dependable drugs is strictly scientific. The use of morphine in pneumonia with violent pleuritic pain; of adrenalin in spasmodic asthma; of alkalis in digestive disorders with hyperacidity: in all these conditions the application of the remedy to the symptom is unassailable from a scientific standpoint.

There is another group of symptoms, however, and another group of drugs, which have become related in one way or another: certain symptoms calling to mind certain drugs, not on scientific grounds, not always on reliable empirical grounds, but by virtue of habit, custom or unjustifiable repetition in the books. Such symptomatic treatment has no standing; and here a thorough revision of therapeutics needs to be made. Perhaps one of the most useful ways to attack this problem would be by teaching students the natural course of untreated diseases.

An authoritative evaluation of symptomatic therapy is of the utmost importance both for the comfort of our patients and also for clearing up the field of experimental therapeutics.

(To be continued.)

Book Reviews.

The Curative Action of Radium. By DR. SIGMUND SAUBERMANN, Charlottenburg, Germany. 1915.

This monograph is the reprint of an address on the progress of radium therapy delivered by the author at a meeting of the Roentgen Society in London on April 1, 1913. It presents the results of his research work on this interesting subject. It is well illustrated with a series of thirty-five half-tone illustrations, eight of which are engravings from photographs.

CARLYLE'S OPINION OF PHYSICIANS.

THOMAS CARLYLE was a man with as positive ideas about doctors as those he held on all other subjects, and his manner of expressing them was equally original and forcible. In her "Memories of Victorian London," quoted in the issue of the *British Medical Journal* for Nov. 30, 1912, Mrs. L. B. Walford recalls a meeting with Carlyle one day during his residence in Chelsea. He was looking ill, but refused to see a physician.

"A friend related the following story: 'Did you ever hear how he turned on a poor country practitioner down at my brother-in-law's place, where he had an attack which frightened everybody, for it was uncommonly like cholera, and cholera was about? My brother-in-law took it upon himself to send for the village doctor, a worthy old fellow with a long-established practice, and you may suppose Aesculapius was not a little flustered and flattered at being summoned to such an illustrious patient. With the utmost alacrity he made his way to the Hall, and was shown upstairs to the patient's bedroom, but

there his self-complacency received a rude shock. My brother-in-law told me he did not know which way to look when a shaggy head uplifted itself from the pillows and peered over the bed-clothes. "Who's that?" He replied that it was the doctor, whom he had thought it right to send for. "Doctor?" thundered Carlyle. "I'm for none of your doctors. Of all the sons of Adam men of medicine are the most unprofitable." "And the poor, unprofitable man of medicine found it impossible to obtain a hearing," said our informant, shaking his head, "and had to retreat ruffled and terrified. The worst of it was that his visit so annoyed and roused the Sage that it put fresh spirit into him, and he began at once to get better, all the time railing at doctors, and triumphantly pointing to his own ease as proving his point against the faculty!"

Carlyle's opinion about doctors, however, was not always of this nature. His own brother was a physician, and in his correspondence, Thomas several times speaks favorably of the profession. At the annual meeting of the British Medical Association in Bristol in 1894, Dr. Yeats presented a letter from Carlyle addressed to his publishers in Edinburgh:—

"It was addressed to a firm of Edinburgh publishers who had sent him a book published by them, written by one who hid his identity under the pseudonym 'Therapeutes':

"Chelsea 25th Feby. 1859.

"Dear Sir—I have received your book which you were kind enough to send me, and I beg to return you thanks for the same. It is a book (unlike many that come to me here) of a serious nature, the fruit of long study, meditation, inquiry, and evidently of perfect conviction on your part.

"I believe, and have long believed, the essential idea it sets forth to be not only true, but of the very highest importance to mankind namely, that the Physician must first of all be a priest (that is to say, a man of pious nobleness devoted to the service of the Highest, and prepared to endure and endeavor for that same taking no counsel of flesh, and blood, as the theory of Priests is),—first of all, a real priest and then that the whole world should take supreme counsel of him, as it does of its real or imaginary Priests or Pontiffs this long while back, and follow said counsel as the actual will of God,—which it would be were the Physician what I say.

"It is curious to remark that Heilig in our old Teutonic speech is both Holy and also Healthy; that the words Holy and Healthy, a our antique fathers understood them, are on, and the same. A thousand times has that etymology risen sorrowfully upon me, in looking at the present distracted position of affairs, which is horrible to think of, if we look earnestly int

t, and which cannot well be spoken of at all. We, sure enough, have completely contrived to divorce holiness (as we call it) from health, and have been reaping the fruits very plentifully during these fifteen hundred years.

"The notion of bringing our present distracted anomaly of a Physician into union with our ditto of a Priest, and making them identical is, of course, extremely chimerical; nor can one easily say what ought to be the first step towards bringing each of them back from his nomalous imaginary condition and nearer to eracity, and the possibility of coalescing. But am very glad to see the idea started, in any form, under any vesture, and heartily wish you success in bringing it home to men's minds.

"I remain, yours truly,

T. CARLYLE."

In a later issue of the *British Medical Journal* (Dec. 7, 1912) is quoted another letter by Carlyle, under date of Jan. 18, 1842, to Dr. James Hutchison Stirling, first published in Miss Stirling's biography of her father.

"Practically, my advice were very decidedly that you *kept* by medicine; that you resolved faithfully to learn it, on all sides of it, and make yourself in actual fact an *ἰατρός*, a man that *could* heal disease. I am very serious in this. . . A steady course of professional industry has ever been held the usefulest support for mind as well as body; I heartily agree with that, and often I have said, What profession is there equal in true nobleness to medicine? He that can abolish pain, relieve his fellow mortal from sickness, he is the indisputably usefulest of all men. Him savage and civilized will honor. He is in the right, he is in the wrong who may. As Lord Chancellor under one's horse-hair wig, there might be misgivings; still more perhaps as Lord Primate, under one's cauliflower; but if I could heal disease, I should say to all men and angels without fear, '*En, ecce!*'"

Apparently his opinion of doctors was really good deal better than might have been inferred from the Chelsea episode.

THREE TYPHOID TREATMENTS.

As long as human psychology remains what it is, the desire for exactness will impel medical investigators to search for specifics. It is, of course, a pleasant thing to be able to make the diagnosis and then prescribe with the knowledge that the disease will crumple up before our attack like a mob before a determined sheriff. Those who have intubated a child about to become asphyxiated with laryngeal

diphtheria and have had the patient sitting up laughing and talking a few minutes later have experienced what is, perhaps, the most striking example of the pleasurable feeling of almost omnipotence that now and then seizes mortals. The popularity of surgery, as well as its appeal to lay minds, is based upon the specific nature of its treatment. It is but natural that typhoid fever, for so many years recognized as a disease entity, should have had its share of investigation with the idea of obtaining a specific treatment. There has grown up a literature on the subject, and one form of therapy after another has had its vogue only to be discarded. The present trend seems to be towards some sort of serum or vaccine treatment, and it is interesting to note that there have appeared recently and almost synchronously the reports of three of these methods, all with apparently good results.

In Germany Dr. Eggreth has reported¹ forty-eight cases treated with Besredka's vaccine, one injection only being given in each case. Thirty-eight of these showed good results, a crisis appearing in from six to ten hours and the temperature remaining normal thereafter. In thirty-four of these cases the temperature stayed normal permanently, in one case there was a slight rise from some unknown cause, and in three cases there were complications which caused some fever. In eight of the forty-eight there were no results apparent from the injection; it is worthy of note that all of these had complications, but all recovered. Two cases died within three hours after the injection, one of these cases had pneumonia and the other intestinal hemorrhage.

Drs. Goldscheider and Angst report² 57 cases treated with dead bacilli, all, according to them, with good results. In each case there was an initial increase in temperature which lasted several days, and then a crisis occurred, with improvement in the clinical symptoms. These doctors state that this treatment is contraindicated in cases with pneumonia, hemorrhage, weak heart or high blood pressure.

In England Drs. Bourke, Evans and Rowland have reported³ the use of autogenous living vaccine with good results. The injection of this is followed by marked constitutional symptoms. There is a sharp increase of temperature during the first few hours, followed by a marked fall twenty-four hours later, together with improvement of the clinical signs. According to

these English investigators this form of treatment cuts short the duration of the disease.

With all the above favorable reports, the physician finds himself with considerable latitude in the way of serum therapy, although it will doubtless be the opinion of most of our profession that sufficient cases have hardly been treated as yet by any of these methods to justify generalities. Moreover, it is to be hoped that the increasing popularity of typhoid vaccination will in time make typhoid fever a clinical curiosity.

PREVENTION OF MOTOR ACCIDENTS.

In the issue of the *Medical Record* for Aug. 7 is an admirable editorial, suggesting the importance and desirability of more adequate examination of automobile drivers before their licensure. If the whole number of lives lost or injuries received each year due to motor-driven cars and boats were published, the large total would be a surprise to most readers. In this day of preventive study it is safe to say means can be adopted, when public opinion is ready to demand it, to make a reduction in this list.

How many intelligent people would risk their lives in a railroad train or steamboat, particularly in search of pleasure, if the pilots and engineers were required to conform to no more physical and mental standards than are required of motor boat or motor car drivers? It is for public protection that boats and trains are run neither on faith, ignorance or under the influence of alcohol, but as they should be by clear headed persons having knowledge of the construction and care of their machines with tested training and experience in the "rules of the road." Railroads and governments do not employ medical examiners for the fun of spending money or the pleasure of annoying engineers and pilots. Yet without all the safeguards demanded of railroads and steamboats, almost any one, normal or defective, may run his own high power motor boat or motor car through public waters or streets.

It is common to hear pilots complain that one of their troubles in the summer months is to keep out of the way or out of harm with a motor boat, run regardless of navigating rules. Also

normal auto drivers have a like experience on the road in trying to puzzle out what the fellow ahead or behind is going to do next. This does not mean that most drivers are in this class, at there are enough to keep the careful nervous.

The time has come when the pedestrian and careful driver ought to be protected. Medical examiners could be appointed through civil service by state or government with adequate salaries to give whole time service by being appointed to districts to examine from time to time persons wishing to run boats or cars and to keep on file official records of all applicants. This would show the number of persons applying that are color blind, deaf, mentally defective, with defective vision or any other nervous or physical defect.

With the information furnished, the licensing board would be able to decide as to what form of permit is to be issued, whether to allow the person to run a high- or low-powered motor. With persons physically fit it ought not to be difficult to weed out the wilful breaker of the road rules and the alcoholic by the court refusing a license or revoking a license in addition to other penalties if such driver was at fault in an accident. This is no more than pilots and engineers have to suffer.

The motor boat and automobile in heavy hands are valuable acquisitions to present fleets and should be encouraged. The pedestrian also still feels a desire to live and keep the parts of his body together if possible.

OLD TESTAMENT MEDICINE.

THERE are many references in the Old Testament to disease, plagues, afflictions, palsies, etc., but these terms often seem to have several different applications or are so loosely used that their meaning cannot be definitely ascertained. In the *Scientific American Supplement* for July 31, Dr. Stuart B. Blakely has published an interesting account of the medicine of the Old Testament. His study of that document seems to have been so thorough that it is impossible here to do more than mention a few of the fruits of his inquiry.

Dr. Blakely asks us to remember that in dealing with the medical annals of the Old Testament we have at hand only the non-mil-

erature of a primitive, nomad race and of the references are obscure to the point of intelligibility to the modern reader. The references to medical topics in Biblical would seem to indicate that the priests were the only doctors among the early peoples. Egypt was famous for its healers, and kings of other countries sent for its physicians when their royal healths became delicate. Ancient Egyptians held that the liver was the source of happiness, which opinion may not be far off after all. The Hebrews possessed skill for hygiene and had numerous laws in relation to personal habits, community sanitation and kindred subjects, which might almost be taken as models even today.

Smallpox is generally supposed to have been prevalent in those days, and yet we find only references to it in the Old Testament, and none of the cases mentioned probably were not disease. Skin disorders, wherever they are general in distribution and chronic in nature, were called leprosy. The term plague, however, seems to be greatly misused by the Biblical writers. We think of it as the bubonic plague, "Black Death," to use the highly picturesque name by which it is commonly known, but in the Old Testament plague is loosely applied to any epidemic where the mortality was great. It does not seem likely that these were all instances of the great Black Death which killed one and a quarter millions in Germany in the middle of the fourteenth century, and 70,000 in London in 1664. On careful analysis of the various plagues mentioned in the Bible, Dr. Blakely comes to the conclusion that four of the five among the Israelites were probably the Black Death. The fifth plague of the Egyptians seems to have been either anthrax or smallpox. The description of the plague of the Philistines reads like typhoid.

DEATH OF TWO EMINENT PHYSICIANS.

THE almost simultaneous death of two eminent physicians and scientific investigators, mentioned in another column of this issue of the JOURNAL, emphasizes one of the inevitable tragedies of peace in the midst of those of war. Dr. Welch was famous chiefly as the inventor of arsphenamine, a synthetic drug which not only is the product of brilliant and patient skill in research, but, as one of the few and most effective

medicinal specifics, also had radically changed and improved the therapeutics and prognosis of syphilis. Dr. Finlay, one and the only survivor, of Reed's original Yellow Fever Commission, not only shared the perils and hardships of the labors of that devoted body, but was really the first to suggest the analogy of yellow fever to malaria as a disease of mosquito transmission. A full account of the lives of these men will appear in an early issue of the JOURNAL. Their death is matter for universal regret, for the benefits accruing from their work are to all mankind without distinction.

MEDICAL NOTES.

EUCALYPTUS IN MENINGITIS.—A press report from Melbourne, Australia, by way of London, on Aug. 11, chronicles an announcement by Dr. Richard Bull, director of the bacteriologic laboratory of the University of Melbourne, that oil of eucalyptus is a specific cocciæ for the diplococcus intracellularis meningitidis. The truth and possible therapeutic value of this observation remain to be determined by scientific report and further clinical study.

PREVALENCE OF MALARIA, MENINGITIS, POLIOMYELITIS, SMALLPOX, AND TYPHOID.—The weekly report of the United States Public Health Service for Aug. 6 notes that during the month of June, 1915, 300 cases of malaria were reported in Arkansas and 1030 in Virginia. During the same period there were in Virginia 19 cases of cerebrospinal meningitis, 20 of poliomyelitis, 115 of smallpox, and 258 of typhoid. In New York there were 33 cases of meningitis, 10 of poliomyelitis, and 255 of typhoid. There were 24 cases of smallpox in California, 35 in Arkansas, 170 in Iowa, and 135 in Texas. There were 54 cases of typhoid in Arkansas, 76 in California, and 109 in Texas.

AMERICAN PUBLIC HEALTH ASSOCIATION.—The forty-third annual convention of the American Public Health Association is to be held at Rochester, N. Y., next week, from Sept. 6 to 10, inclusive. In conjunction with this meeting will be held also the fifteenth annual conference of the Sanitary Officers of New York State. The present officers of the American Public Health Association are: President, Prof. William T. Sedgwick of Boston; vice-presidents, Dr. C. J. Hastings of Toronto, Dr. Juan Guiteras of Havana, Cuba, and Dr. C. E. Terry of Jacksonville; secretary, Prof. Selskar M. Gunn of Boston; and treasurer, Dr. Lee K. Frankel of New York.

In his call for this meeting Professor Sedgwick said: "This year we must beseech all the Americans to prepare to deal with unusual invasions of minute, mostly invisible, but often multitudinous and powerful enemies. We must defend American cities and American homes against typhus as well as typhoid, against Asiatic cholera as well as smallpox, and against bubonic plague as well as dysentery. Meanwhile, cancer and inanition, poverty and unemployment, gluttony and intemperance, uncleanness, bad air and perverted appetites will not abate, but rather exacerbate their activities because of war and its evil influence upon public health."

At the opening session Professor Sedgwick will deliver his presidential address on "Achievements and Failures in Public Health Work." The meetings of the six sections, composed respectively of health officers, laboratory workers, vital statisticians, sanitary engineers, industrial hygienists, and social workers, will deal in appropriate symposia with various problems of public health education, milk, death rates, administrative control of infectious diseases, infant mortality, the practical use of municipal vital statistics, sewage disposal, industrial morbidity and mortality, and control of venereal diseases. Among the Massachusetts physicians who will present papers are the following: Dr. F. G. Curtis of West Newton on "Is the Control of Measles and Whooping-Cough Practicable?"; Dr. G. W. Simons, Jr., of Boston on "Garbage Disposal in Small Towns"; and Dr. William H. Davis of Boston on "The Registration of Non-Resident Deaths." "Efficiency in the Worker and Its Maintenance" will be discussed by Dr. W. I. Clark of Worcester.

EXPECTATION OF LIFE IN VARIOUS COUNTRIES.
In a recent issue of the *Journal of State Medicine*, quoted in the *Boston Transcript* of Aug. 11, the superintendent of the Scottish statistical department compares the expectation of life of male and female infants in various countries, as shown in the following table:—

Country	Date.	Male.	Female.
Scotland	1891-1900	44.68	47.44
Scotland	1881-1890	43.92	46.33
Scotland	1871-1880	40.95	43.80
Scotland	1861-1870	40.33	43.85
Sweden	1901-1910	54.55	57.00
England and Wales*	1910-1912	51.50	53.35
Norway	1891-1900	50.41	54.14
Denmark	1895-1900	50.20	53.20
Scotland	1911	46.33	50.14
Holland	1890-1900	46.20	49.00
France	1898-1903	45.74	49.13
Belgium	1891-1900	45.39	48.84
England and Wales.	1891-1900	44.13	47.77
Massachusetts	1893-1897	44.09	46.61
Finland	1891-1900	42.90	45.60
Italy	1899-1902	42.83	43.17
Germany	1891-1900	40.56	43.97
Austria	1900-1901	37.77	39.87

* From a table not yet published.

BUBONIC PLAGUE IN HAVANA.—A case of bubonic plague was reported in Havana on Aug. 16, the first since the outbreak of the disease in that city last winter.

HOSPITAL BEQUESTS.—The will of the late Christine Kean Griffin, of New York City, who died on July 29, was filed on Aug. 16 for probate. It contained bequests of \$1000 to the Bellevue Hospital Training-School for Nurses, and \$500 to the New York Infirmary for Women and Children.

AWARD OF BAUMGÄRTNER PRIZES.—It is announced that the Vienna Academy of Sciences has awarded its Baumgärtner prize to Dr. Heinrich Rubens, of the University of Berlin, and to Dr. Wilhelm Trendelenburg, professor of physiology at Innsbruck.

IMPERIAL CANCER RESEARCH FUND.—At a recent meeting of the general committee of the British Imperial Cancer Research Fund, Dr. Sir Rickman J. Godlee was elected a member of that committee, and Dr. Sir Thomas Barlow a member of the executive committee.

SOCIETY FOR THE STUDY OF INEBRIETY.—A meeting of the Society for the Study of Inebriety was held in London on July 13. Major Leonard Darwin, president of the Eugenics Education Society, delivered the principal address on "Alcoholism and Eugenics."

EUROPEAN WAR NOTES.

RUSSIAN BARBER SURGEONS.—Report from Berlin on Aug. 19 states that, owing to the present paucity of surgeons in Russia, a large number of barbers, after six weeks' of medical training, have been drafted and assigned to duty as surgeons with the Russian army. If true, this statement indicates an interesting example of surgical atavism.

CANADIAN HOSPITAL UNITS AT DARDANELLES.—Report from London on Aug. 19 states that three hospital units recently sent out from Canada to England have been safely transported aboard the *Asturias*, two to the Dardanelles and one to Cairo, Egypt.

DEATH OF AN AMERICAN PHYSICIAN ON THE ARABIC.—Of the two Americans reported to have perished at the sinking of the *Arabic*, one was a physician, Dr. Edmund F. Woods, of Jamesville, Wis. Dr. Woods went to England last fall and had spent the winter and spring at London engaged in Red Cross work.

ENGLISH HOSPITAL TRAIN.—The following is a recently published description of a hospital train devised by the Great Eastern Railway of England, to convey wounded soldiers from the battlefield to hospital:—

"It consists of nine passenger cars of the usual English or Continental type, about fifty-five feet long. Five are used for wards with twenty beds each, two are the dormitories of the medical staff, one is the dispensary and operating room and the ninth is the kitchen-dining room. In the case the side-doors are fastened, excepting the double ones of the baggage compartment, the partitions and seats are removed, and the beds ranged along the walls in two tiers, each one movable so that it can be properly made up, and when in place a central aisle in the ward is afforded of nearly three feet in width. The windows are shaded by curtains, and the gas lights screened. The ward flooring is covered with linoleum and those of the toilets with lead and a white enamel paint used on the wood work everywhere.

"The service car has several compartments, for clean linen, soiled clothing, etc., an operating room, a pharmacy, the water is heated by means of a gas stove, and a fresh water tank is installed at the ceiling. The dining car may be converted into a dormitory at night, having disappearing tables, and the capacity for sleepers is ten. There is steam heat throughout, and what railway trains in general need almost everywhere, fresh air well distributed. The exterior is decorated with the Red Cross."

CHOLERA IN WÜRTEMBERG.—Report from Geneva, Switzerland, by way of Paris, states that a case of Asiatic cholera has recently occurred at Cannstadt, Würtemberg, in the person of a German soldier recently returned from Galicia. Precautions are being taken in the canton of Neuchâtel, Switzerland, to prevent the introduction of the disease into that country from across the Austrian frontier.

BOSTON AND NEW ENGLAND.

SUPERVISION OF INDUSTRIAL HYGIENE.—An excellent work has been quietly done during the past few years by the Boston Association for the Relief and Control of Tuberculosis in the organization of clinics in factories, mills, stores and mercantile establishments, under the supervision of a visiting physician and a nurse. This movement is not only for the benefit of employees, but for the protection of the general public against various communicable diseases which may be transmitted through products of manufacture. The advantages of this medical supervision of health in factories are the early detection of disease, adaptation of work to the physical condition of the individual, and protection of fellow-employees from contagion. The advantages to the employer are in the greater efficiency of labor, greater content of workers, increased coöperation, and diminished loss of time from preventable diseases. The advantages to the general public are seen chiefly in the various food industries.

Obituary

EDMUND OWEN, M.B. (LOND.), F.R.C.S.,
LL.D. (ABERD.), D.Sc. (SHEF.)

MR. EDMUND BLACKETT OWEN, who died of cerebral hemorrhage on July 23, 1915, in London, was born at Finchamfield, Essex, England, on April 7, 1847, the son of a physician. After obtaining his preparatory education at Bishop's Stortford and King's College, London, he began his medical training in 1863 at St. Mary's Hospital in that city. Later he studied in Paris, and in 1868 qualified as M.R.C.S.

From the outset, anatomy and surgery constituted his greatest interest, and as early as 1867 he was appointed demonstrator of anatomy at St. Mary's. In 1871 he became surgeon to outpatients at that institution. In 1872 he received the degree of M.B. (Lond.) and qualified as F.R.C.S. He was appointed lecturer on anatomy at St. Mary's Hospital Medical School in 1876; and in 1877, assistant surgeon to the Ormond Street Hospital for Sick Children. He became full surgeon at St. Mary's in 1882, and at Ormond Street in 1883. From 1888 to 1896 he was lecturer on surgery, in succession to Mr. A. Trehern Norton. He became consulting surgeon at Ormond Street in 1898 and at St. Mary's in 1902. He was also for a time surgeon to the French Hospital, London, and consulting surgeon to the Paddington Green Children's Hospital.

From 1905 to 1907 Mr. Owen was vice-president of the Royal College of Surgeons of England. In 1906 he delivered the Bradshaw Lecture on "Cancer: Its Treatment by Modern Methods"; and in 1911, the Hunterian Oration. In 1899 he was president of the section of diseases of children of the British Medical Association at its meeting in Portsmouth, and in 1903 president of the section of surgery at the meeting in Swansea. He was president of the Harveian Society and of the Medical Society of London.

Mr. Owen was a prolific writer on surgical topics. His text-book on "The Surgical Diseases of Children" was published in 1885, and went through three editions and a French translation. In 1890 appeared his "Manual of Anatomy for Senior Students," and in 1904 his "Cleft Palate and Hare Lip." He was author of the article on surgery in the eleventh edition of the *Encyclopædia Britannica*.

In recognition of his distinguished ability as a surgeon, teacher, and writer, Mr. Owen received honorary degrees from the Universities of Aberdeen and Sheffield, and was a Chevalier of the French Legion of Honor. He was correspond-

ing member of the American Orthopedic Association, the Canadian Medical Association, and the Imperial Medical Military Academy at Petrograd.

Of athletic and vigorous physique, Mr. Owen always maintained an active military interest, and at the outbreak of the present European War became surgeon-in-chief of the St. John Ambulance Brigade. In this capacity he established and organized the Epsom and Ewell War Hospital, and was intimately engaged in its work from last October until his death. He is survived by four daughters.

Mr. Herbert Page, writing of Owen in the issue of the *Lancet* of July 31, speaks as follows of his personality and of his characteristics as a surgeon:—

"His works on the surgical diseases of children, on cleft palate and harelip, and on club foot are, of course, known to everyone, and in these departments he was a recognized authority. Here as an operator he was doubtless seen at his best, while in general surgery there was marked distinction in his work. There was nothing which he feared to undertake, and difficulties, when they arose, were overcome by his courage and resourcefulness and by his knowledge of anatomy, in which he had been a teacher for many years. If onlookers might criticize they would, perhaps, have said that he gave too little thought to loss of blood, and he, of all men, honest to the backbone, would have least liked that this should not be said if it were generally believed. At first he took up an attitude of opposition to Listerian antiseptic methods, and poured contempt, both oral and written, on the ritual of the spray. He even went further than this, and at one of the societies, I think the Medical, when Lister brought forward his open operation for fractured patella, Owen, with characteristic temerity, remarked in parody of the famous saying, that it might be magnificent, but it was not surgery. His papers and addresses on innumerable subjects were always pointed and suggestive.

"The record of his long service to St. Mary's, both as a surgeon and teacher, it is not easy to condense in words. An incisive speaker, with a marvelous store of apt illustration, he was a born teacher, as hundreds of students would amply testify. There was nothing anywhere quite like Owen's class in the theatre at the close of operations; by informed questions, by encouragement and sympathy, by veiled irony and gentle ridicule, by humorous invective, by instructive anecdotes of professional experiences, he seemed to draw all the boys unto him, and not even the most stupid of 'chronics' was afraid to go to the class again. Then the transparent honesty of the man, shown not least in an impulsiveness which led him to hasty conclusions, soon to be put aside, so that he would vote tomorrow against that which he had advocated today. You forgave, you laughed, and loved him

the more. And now his life here is run, and we lay this garland on his hearse. His memory will long abide, as that of a fine Englishman, fearless, independent, straight, free from self-seeking, held in respectful veneration by countless students, trusted by his colleagues, and withal a most lovable man."

In the issue of the *British Medical Journal* for July 31 is also the following estimate of Owen's character by Mr. F. Richardson Cross, of Bristol:—

"In the passing of Edmund Owen the profession of surgery has lost one of its leaders, respected for his uprightness and high sense of duty, and honored for the active part he has taken in medical ethics, and in the progress and improvement of surgical practice and in its fine teaching. He was endowed with good health and a fine physique. His personality and ability as a student soon attracted the attention of his seniors, and he made an unusually early entry into important positions in the profession. This early recognition was not misplaced, for he rapidly became one of the most popular teachers both in anatomy and surgery. He was a well known figure in his earlier days at several meetings of the British Medical Association. I went with him to America on the occasion of the Congress at Washington in 1887, and ten years later to St. Petersburg, when we represented the Royal College of Surgeons of England at the celebration of the centenary of the foundation of the Russian Army Medical Service, and at which an enormous number of delegates from all parts of the world were present. We had the especial honor of being in a small party of European surgeons who were, one by one, received in conversation by H. I. M. the Czar and afterwards took lunch with General Kuropatkin. Owen was always in good spirits, courteous, and amusing, but not at the expense of others. I never remember his saying an unkind word of any colleague, and he showed no unfair bias against opinions he did not agree with. If he could not speak well or kindly of men or matters he did not discuss them. He was a hard worker. He wrote and spoke forcibly and well. Perhaps by nature somewhat impulsive, he carefully considered his subject with ability, shrewdness, and common sense, and, having formed his opinion, he was fearless and honest in expressing his views, which were usually sound and accurate. His work for the Royal College of Surgeons as an examiner and on the council was whole-hearted and of the highest value. He had been an active member of all the subcommittees, and the personal knowledge and long experience that he had of its affairs made him one of its most trusted leaders. He has been spared from old age, and has gone down at his post and in his work."

Miscellany.

LARREY'S EXPERIENCE WITH FROST BITE.

IN the issue of the JOURNAL for January 21, we published an item describing Larrey's personal experience in the Battle of Waterloo. The *British Medical Journal* in commenting on the frequency of frost bite during the present trench warfare in Flanders has recently referred to Larrey's experience on this subject. In the third volume of his *Mémoires de Chirurgie Militaire*, Paris, 1812, Larrey devotes a special chapter to the subject of gangrene caused by cold.

"This *gangrène de congélation*, as he calls it, was one of the worst troubles the surgeons had to deal with after the battle of Eylau, which was fought on February 8th, 1807. Only a small number of the men of the advanced guards escaped. In some the gangrene was limited to the epidermis of the toes or heels; in others the mortification attacked the tissue of the skin more deeply over a greater or smaller extent, causing the loss of toes or of the whole foot. Larrey notes that although for some days before and after the battle the men had been exposed to the most severe frost, they did not suffer in their extremities. The Imperial Guard, in particular, had stood in the snow, hardly moving for more than twenty-four hours, yet not one of the men had his feet frozen. Then suddenly the temperature rose several degrees and a thaw set in. At once a number of the men felt intense pain in the feet and numbness, heaviness and tingling in the extremities. The affected parts were dark red in color, but not much swollen. In some cases there was slight redness towards the base of the toes and on the dorsum of the foot; in others the toes had lost movement, sensibility, and heat, and were already blackened and dried up. Those who went to the fires of the bivouacs to warm themselves suffered most; the wounded in the field hospitals escaped because they had no chance of doing this. The progress of the disease was rapid, but it seldom extended beyond the toes and only rarely spread above the malleoli. Larrey insists that sphacelus of the foot must not be confused with gangrene of the skin. It often happened, he says, that a greater or less extent of the skin of the foot became mortified, without the vessels, deep nerves, tendons, ligaments or bones becoming gangrenous; in that case the patient felt pain when the subjacent parts were touched, but he could move his feet, and the internal heat was preserved. Sphacelus, on the other hand, deprived the limb of movement, sensibility, and all the properties that characterize life; the patient could not feel his foot, and it seemed to him that a foreign body hung to his leg. If the mortification was superficial, the eschars usually became detached between the ninth and thirteenth days, leaving a sore which quickly healed. If the whole of the limb was necrosed the patient succumbed to the

sepsis which followed the separation of the eschars.

"Larrey expresses the belief that unless the patient has been exposed to the influence of the cold long enough to produce local asphyxia, and unless a second 'sedative or narcotic cause' such as alcohol is coöperating with it internally, the partial or general gangrene does not occur while the cold lasts. Travellers pass the Alps and the Pyrenees in the most rigorous cold without evil consequences as long as the temperature does not change. The Poles choose the time when the frost is likely to last to go on long and difficult journeys by caravan, but they dread such journeys at the times when the temperature is variable. During Napoleon's campaign in Holland a large number of men had their feet 'frozen,' but this happened only when thaw set in. Larrey, therefore, holds that cold is only a predisposing cause, the sudden application of heat being the determining factor. When the affected parts have already lost mobility and natural heat, and sensibility is blunted, frictions with snow and melted ice are the best means of exciting the paralyzed vessels to healthy action. He recommended that the circulation should be maintained by the successive application of spirituous and camphorated tonics, the gradual administration of cordials internally, dry and hot friction over all the body, and continuous but moderate exercise. If there were no snow or melted ice handy he advised that coarse cold red wine, vinegar, and camphorated brandy, made cold by plunging it into spring water should be used instead. In hopeless cases amputation when the line of demarcation had formed was, he said, the only course open to the surgeon."

Correspondence.

EUGENICS AND MODERN WARFARE.

BOSTON, August 27, 1915.

Mr. Editor: In an editorial in the issue of the JOURNAL for Aug. 26 you present most ably one side of the question of the eugenic, or rather dysgenic, effect, of modern methods of warfare.

On the other hand, it is probably true that other aspects of the question ought also to be considered. For better or for worse civilization has hitherto advanced, and on the whole grown better, in spite, if not as a result, of war. War between nations is after all only one manifestation of the animate struggle for existence, so impersonal, relentless, and cruel among the lower animals, yet nevertheless a biologic phenomenon even among men.

As a matter of fact war does not kill or hopelessly cripple all the best men who engage in it. Some of the young and vigorous survive to have children, and some have left issue before going to their death. It is commonly alleged that a war injures the victorious nation more than the vanquished, yet there are examples in history to the contrary. Caesar found the Belgians the bravest of all Gauls; yet, though their land, the cockpit of Europe, has been drenched with blood for nineteen centuries, their race has remained prolific, hardy, and seems to have lost none of its virtue and sturdy physical and moral qualities. Moreover, the example of France has shown the tremendous regenerative powers of nature, in races as well as in individuals.

Perhaps, in the long run, a peaceable nation suffers more, eugenically speaking, from war than does a belligerent people; and the experience of time seems to have shown that ultimately the race which can beat another in war is really the superior, mentally and physically, and will survive, at least until it succumbs to other adverse conditions. Doubtless a great war is always a great calamity, yet it is one which civilization has always hitherto survived. Indeed, it is an arguable question whether civilization itself does not sometimes involve evils more perilous to the race, from a eugenic standpoint, even than those of war, which seems and in fact is, the temporary negation of civilization.

After all, this question, like many others, seems hard to settle by *a priori* theory or opinion. The thing which really makes the present European War by far the most momentous in history is not its extent and intensity, but the fact that it is probably going far to answer, by the experimental method, so many problems, biologic, eugenic, moral, philosophic, political, social. It is a costly experiment, but, since it has befallen, should hopefully be regarded not as a fatal catastrophe.

Very truly yours,

AUDI ALTERAM PARTEM.

AMERICAN SURGEONS IN FRANCO-PRUSSIAN WAR.

18 WEST CEDAR STREET, BOSTON.

Mr Editor: May I inquire through the JOURNAL if any of your readers know of American doctors who were in the Prussian service in the Franco-Prussian War? I was stationed at Pont-à-Montion, 17 miles from Metz. Dr. Avery, now or recently living in Brooklyn, N. Y., was with me, but I can learn of no other surviving.

SOCIETY NOTICE.

ESSEX NORTH DISTRICT MEDICAL SOCIETY.—A quarterly meeting of the Essex North District Medical Society will be held at the Danvers State Hospital, Hathorne Station (Tel. Danvers 37) Wednesday, Sept. 8, 1915, at 4 P.M. sharp, upon invitation of Dr. Kline, Superintendent.

The meeting will be held jointly with the Essex South, and Dr. C. F. Withington of Boston, president of The Massachusetts Medical Society, has accepted an invitation to be present.

Paper will be presented as follows: Dr. H. A. Hare, of Philadelphia, Professor of Therapeutics and Diag-

nosis in Jefferson Medical College, upon "Certain Facts of Interest About the Cardiovascular System." Free discussion desired (five minutes each).

A buffet lunch will be served after the meeting.

Let us have a large attendance to welcome our illustrious speaker and to enjoy pleasant social intercourse with Essex South under the roof of Dr. Kline's splendid hospital.

The next meeting of the Censors will be held at Hotel Bartlett, Haverhill, Thursday, Nov. 11, 1915, at 2 P.M. sharp. Candidates for admission to the Society should bring their diploma.

The Committee on Membership of this Society invites and desires the members to invite every conscientious, skillful physician, eligible to membership in the Society, and residing within its jurisdiction, to appear before the Censors of Essex North at their meeting on Nov. 11, 1915.

V. A. REED, M.D., President.

J. FORREST BURNHAM, M.D., Secretary,
99 Bradford Street,
Lawrence, Mass., August 31, 1915.

RECENT DEATHS.

DR. AMMI WARD FOLLETT, of Somerville, Mass., died at his home in that city, August 15, aged 57 years. He was born in Royalton, Vt., January 27, 1858, was graduated from the Dartmouth Medical School in 1881 and was for five years assistant superintendent of the Butler Hospital, Providence. Dr. Follett had practised in Somerville since 1888. He was a Fellow of The Massachusetts Medical Society and of the American Medical Association and was a Mason. He is survived by a wife and two sisters.

DR. PAUL EHRLICH, who died of heart disease on Aug. 20 at Bad Homburg, was born in 1854. He was famed as the inventor of salvarsan; and in 1908 was awarded one-half of the Nobel prize in medicine for that year.

DR. CHARLES E. FINLAY, who died on Aug. 21, in Havana, Cuba, was born at Camaguey in 1833. He was a member of Reed's original Yellow Fever Commission, in 1898, but had retired from his profession, some time ago.

DR. JAMES CHARLES FAHEY died at Northampton, Mass., August 24, aged 48 years. He was a graduate of the University of Vermont College of Medicine in 1891 and had practised in Northampton since that date, being a Fellow of The Massachusetts Medical Society and of the American Medical Association. He was city physician from 1896 to 1900. He is survived by a widow and three children.

DR. JOSEPH LAWRENCE HICKS, who died recently at Flushing, Long Island, N. Y., was born in 1834. After graduating from the Polytechnic School at Troy, N. Y., he received the degree of M.D. from the New York College of Physicians and Surgeons. For many years he was visiting physician to the Flushing (L. I.) Hospital, until his retirement in 1911.

DR. EDMUND F. WOODS, who died at the sinking of the *Arabic* on Aug. 19, was born at Aldborough, Norfolk, England, in 1854. Coming to the United States in 1860, he obtained his early education in Ohio and Wisconsin. He obtained the degree of M.D. in 1880 from the Indiana Medical College, and until 1889 practised his profession in Darlington, Wis. He then removed to Janesville, Wis., where he continued until the outbreak of the European War. He is survived by his widow.

APPOINTMENTS.

UNIVERSITY OF NEBRASKA.—Dr. Max Morse has been appointed assistant professor of biochemistry.

WESTERN RESERVE UNIVERSITY.—Dr. William Evans Brunner has been appointed professor of ophthalmology; Dr. H. H. McGregor, instructor in ophthalmology; Dr. C. D. Christie, director of the clinical research laboratory; and Dr. Russell J. Collins, demonstrator of pharmacology.

LATE RESULTS OF OPERATIONS FOR CORRECTION OF FOOT DEFORMITIES RESULTING FROM POLIOMYELITIS.

BY HERMAN W. MARSHALL, M.D., BOSTON,

AND

ROBERT B. OSGOOD, M.D., BOSTON.

[From the Orthopaedic Clinic of the Massachusetts General Hospital.]

TWENTY-SIX cases were selected for this study from among many patients treated at the Massachusetts General Hospital. All simple tenotomies of the tendo Achillis for equinus deformity, all plantar fasciotomies for slight contractions of the feet, all recent cases of all sorts were discarded and only the more complex ones of longer duration retained. All patients within this restricted class, however, that came back for final observation are included, both good and bad results. The number of cases is small because the orthopaedic ward of the hospital was not opened until November, 1907, and only a few years of patients' admissions, therefore, are available. The average length of time that has elapsed since operative interference among the twenty-six cases reported is four years and ten months; and it is interesting to note how widely the older patients have scattered, in this particular series scarcely a half of them being able to return for observation.

The cases show the results of seven astragalectomies, six arthrodeses of ankle joints, numerous tendon transplantations, arthrodeses of small joints of the feet, tenotomies, fasciotomies and osteotomies, but it is to be regretted that there are included none of the tendon fixations recently advocated by Gallie.

Group statistics will be presented first, followed by individual histories, and finally a few brief conclusions will be drawn. In detail the varieties of surgical procedures were as follows, and their different combinations will be seen in the individual records of patients.

Five cases of tendo Achillis lengthening or tenotomy.

Five cases of plantar fasciotomy.

Seven cases of tibialis anticus tendon transplantation for varus deformity.

One case of tibialis posticus tendon transplantation for previously over-corrected valgus deformity.

One case of tibialis posticus tendon transplantation into a weakened tendo Achillis.

Five cases of peroneal tendon transplantation for valgus deformity.

Five cases of peroneal tendon transplantation into weakened tendo Achillis.

Six cases of extensor longus hallucis tendon transplantation laterally into head of first metatarsal bone for hyperextension and flexion of the great toe.

Two cases of arthrodesis of the first phalangeal joint of the great toe associated with transplantation of extensor longus hallucis tendon.

Nine cases of arthrodesis of smaller joints in connection with tendon transplantation, e.g. cal-

caneo-cuboid joint, five instances; astragalo-scaphoid joint, four instances.

Five cases of osteotomy, *e.g.* os calcis, two instances; astragalus, two instances; external cuneiform bone, one instance.

One case of insertion of a silk ligament from the tibia to the tarsus for valgus deformity.

There were four examples of calcaneus deformity, five of marked equinus, ten of decided varus, and twelve of valgus defects.

Four calcaneo-valgus deformities ended as follows: (1) A poor functional result from increased instability of the foot following transverse osteotomy of the os calcis and transplantation of peroneal tendons into the tendo Achillis. There was partial correction, however, of the anatomic defect. (2) Slight functional improvement from an astragalectomy, but the patient was obliged to wear a long leg brace because of knee weakness. (3) A fair degree of improvement after an astragalectomy. The patient wears now only a leather ankle support. (4) An excellent result with nearly complete correction of deformity; very good stability, and no braces needed after astragalectomy.

Seven astragalectomies showed useful, very stable feet in four cases, slight instability in two cases, and serious instability in one instance.

Arthrodeses of the ankle joint yielded solid useful ankles in good position three times. One was stable and useful with a few degrees of motion in the joint. Two relapsed into their former bad conditions, and one of the two was followed by a successful astragalectomy.

Five tendo Achillis lengthenings and tenotomies showed two perfect results, and three improvements from partial corrections; and no bad terminations.

Five tendo Achillis strengthenings exhibited partial restorations of strength in four of the five instances. The fifth was no worse than in its original state.

Ages at times of operation varied between four and a half and thirty-eight years, averaging sixteen. Eleven were males and fifteen were females. None was operated upon until three years or more had elapsed after the onset of the paralysis. The latest result is shown in a thirteen year old girl, now eight years and one month after operation. The earliest result recorded is that of a girl of five years at time of operation, and two years and six weeks had elapsed when the last observation was made.

Post-operative Care. The weakest link in a chain of therapeutic procedures determines the strength of the whole and the degree of success of final results; also surpassing merits of certain individual links in the series do not compensate for weaknesses in other ones. Obviously, therefore, it is necessary for fair judgments to include in consideration of results the after treatment which all patients received.

All patients of the series had their feet and legs supported in plaster casts immediately after operation, and, as soon as the wounds were

found to be healing satisfactorily, all were sent home to report periodically at the out-patient department of the hospital. They came back walking with crutches, their operated feet held in corrected positions without having borne weight. Casts were split then, and massage, exercises and bakings prescribed, or in some instances iron foot braces were fitted and medico-mechanical treatments given while the feet were thus held. Crutches were discarded gradually as weight-bearing became gradually possible. Weight-bearing was begun late as a rule, sometimes just before the plaster casts were taken off, not until a month had elapsed after operation generally, and modified greatly according to circumstances. In the earliest instances casts were split and bivalved five or six weeks after operation, but frequently ten weeks elapsed before they were cut, and the longest periods were three months and a half.

Complete removals of casts ranged from six weeks to five months when no braces subsequently were to be worn, the average time being three months after operation. When braces were needed for a while they were substituted for casts on an average of four and a half months after operation, but these times for changing from one form of support to the other varied also between limits of six weeks and nine months. One long leg brace that is being worn at the present time was not fitted until four years had elapsed after the surgical treatment, owing to other complicating conditions.

Patients' records show that braces sometimes were worn for a period and then were discarded. This happened with five persons who wore their supports from six months to four and a half years before leaving them off, showing an average length of time of sixteen months that the leg irons were used.

Medico-mechanical treatments were instituted usually as soon as casts were made removable, but the ease with which regular returns to the hospital were possible influenced these physical therapeutic measures greatly. One patient received eight treatments in nine months, while another had fifty in three months, and many obtained none. Nine only of the twenty-six patients received massage, baking and supervised exercises regularly.

Durations of supervisions are important factors in final results, because old deformities may return very gradually without pain and without incapacitating individuals, so that the only safe efficient course for patients consists in submitting to occasional examinations from time to time. Seven of the twenty-six patients in the series were not lost track of for more than a few months at any time after their departure from the hospital ward. The others returned rather irregularly and more or less as they thought the circumstances warranted, the average length of time which they were under observation being sixteen months, varying between extreme limits of six weeks and four years. Poor results re-

ported by patient eighteen in the table may possibly be due to the fact that he was not seen but twice during the six weeks following his operation, just long enough to have fitted an arthrodesis brace, after which he was not heard from until written to for the final report.

The last statistics show that nine patients who had been wearing iron braces previously had finally discarded them after operation. Twelve who had worn no apparatus before, except foot plates or simple ankle supports, continued to wear nothing more after surgical care than they had previously used. Their improvements consist simply in partly correcting the existing degrees of deformity. More apparatus was required after operation by five persons, usually because improved foot conditions permitted more weight bearing, so that in consequence weakened knees required the support of long leg braces.

CONCLUSIONS.

Twenty-three patients from the total number of twenty-six were distinctly improved after their surgical experiences, although such results perhaps will seem rather unexpected to persons who have witnessed and made comparisons between healthy normal individuals and results of operations seen in infantile paralysis cases. Poor as some operations appear to be at first glance when judged from this standpoint, nevertheless they usually show increased usefulness if compared with previously more deplorable conditions that existed in each instance. Patients themselves agree with these medical judgments, and errors in the casual observations of disinterested persons rather than inefficiencies of surgi-

cal procedures must be held responsible for many bad impressions received of results of operations.

Among the twenty-three beneficial results there were four excellent ones, ten good ones, six that showed moderate improvement and three with slight betterment.

One of three unsuccessful results may be explained, in part at least, as due to this patient's neglect and failure in having post-operative supervision. He relapsed into his former condition and the other two seem slightly worse than previously to their operations.

It is of interest to observe that there were no overcorrections of deformities following tendon transplantations in this series, the usual result being partial correction accompanied by some functional improvement and with only occasional perfect success and complete restoration of function. Over-correction of deformities, however, occur, as demonstrated by the single previously overcorrected case, which was subjected to a second corrective operation to overcome the first bad result.

These late conditions indicate in a general way what may be expected from surgical treatments of fairly complicated infantile paralysis cases in a large hospital where there are a number of different operators and division of responsibilities in the after-care of patients. These statistics, however, are far too meagre and incomplete to possess weight in comparison between individual control of patients from beginning to end and coöperative direction of treatments by groups of physicians. All that can be said is that with a fair degree of coöperation methods herein described have proven themselves reasonably safe and successful.

LATE RESULTS OF OPERATIONS UPON FOOT DEFORMITIES FOLLOWING INFANTILE PARALYSIS.

No. 1. THIRTEEN-YEAR OLD GIRL.

MAIN POINTS OF OPERATIONS.	CONDITIONS BEFORE OPERATIONS.	OBJECTIVE CONDITIONS AFTER OPERATIONS.	SUBJECTIVE FUNCTIONAL RESULTS.
Tibialis anticus tendon transplanted into the arthrodesis line between the os calcis and cuboid bone.	Moderate varus deformity. Peroneal muscles and extensor communis digitorum very weak. Good strength in tendo Achillis group, also in adductors of the foot. Moderate cavus. For a short time a foot brace was worn, then it was discarded because no improvement was observed by mother to result from its use. Duration of paralysis, four years.	Six years and one month after operation the foot is slightly undercorrected. There is good stability in weight-bearing position and no brace is needed. Dorsal flexion of the foot is possible to a right angle passively. No voluntary dorsal flexion. Slight varus and cavus deformity still persist.	The patient is pleased because she can walk better. The foot is in much better position, with no appreciable tendency at present for the deformity to grow worse.

No. 2. EIGHT-YEAR OLD BOY.

MAIN POINTS OF OPERATIONS.	CONDITIONS BEFORE OPERATIONS.	OBJECTIVE CONDITIONS AFTER OPERATIONS.	SUBJECTIVE FUNCTIONAL RESULTS.
Tibialis anticus tendon transplanted into the arthrodesis line between the os calcis and cuboid bone.	Moderate varus deformity and slight equinus. Peroneal group of muscles very weak. Tendo Achillis group normal. Tibialis anticus and tibialis posticus very strong. A varus foot brace was necessary. Duration of paralysis, five years.	Three years and eight months after operation the foot is slightly undercorrected, showing a little varus deformity and some calluses along its outer margin. Stability is good in weight-bearing position. Dorsal flexion is possible passively to a right angle, but voluntary motions dorsally are slight. No voluntary adduction or abduction of the foot.	The patient considers his operation a great benefit because he is able to walk well and work regularly now. There has been marked improvement in position and a brace is no longer required.

No. 3. SEVENTEEN-YEAR OLD GIRL.

Tibialis anticus tendon transplanted into periosteum of os calcis. Osteotomy of os calcis and arthrodesis of calcaneo-cuboid joint.	Moderate varus deformity with slight equinus, also slight hyperextension of great toe. Peroneal group of muscles weak. Tendo Achillis group of muscles of moderate strength. Tibialis anticus and extensor communis digitorum strong. Voluntary dorsi-flexion and adduction of foot possible. Operation advised after ether manipulation and corrective plasters had failed. Duration of paralysis, fourteen years.	Four years and one month after operation the foot still remains slightly undercorrected. The same hyperextension of the great toe exists. The standing position is very stable with some varus deformity and adduction of the forefoot. There is no voluntary dorsal flexion, but passively the foot can be pushed up with some resistance to a right angle. A foot plate is worn to take the pressure off the head of the first metatarsal bone.	The patient thinks the operation is some benefit because the shape of the foot has improved and she can walk as much as desired. The foot is very serviceable.
---	---	---	--

No. 4. EIGHTEEN-YEAR OLD GIRL.

Tibialis anticus tendon transplanted into arthrodesis line between os calcis and cuboid bone. Extensor longus hallucis tendon transplanted into head of first metatarsal bone. Plantar fasciotomy.	Slight varus and slight equinus deformity. Hyperextension of great toe. Walked with a toe dragging gait. No braces worn. Muscle weakness confined mainly to peroneal group. Good strength in tendo Achillis group, also in tibialis anticus and extensor communis digitorum. Plantar fascia contracted. Duration of paralysis for many years.	Six years and nine months after operation the patient reports by letter that there is still slight undercorrection of the original deformity, but she can voluntarily raise the foot dorsally a little better than she could. No apparatus is worn. She disappeared from hospital supervision four months after operation with the foot in good position and wearing no plaster nor any iron support.	The patient says that the operation has been a little benefit. From medical standpoint the increase in voluntary motion probably signifies good function in the transplanted tibialis anticus muscle. Nothing is stated about the great toe deformity, and presumably it is at least no worse. Probably the result represents some improvement.
--	---	---	---

No. 5. TWELVE YEAR OLD BOY.

Tibialis anticus tendon transplanted under annular ligament into internal cuneiform bone. Tenotomy of tendo Achillis.	Moderate varus and moderate equinus deformity. Had callus under cuboid bone and slight contracture of tendo Achillis. Never wore foot brace. Duration of deformity ever since he began to walk.	Three years and four months after operation the foot is in perfect weight-bearing position, although very slight adduction of the foot remains passively. Dorsal flexion possible voluntarily to a right angle.	The patient thinks the operation a great benefit.
---	---	---	---

No. 6. THIRTEEN-YEAR OLD GIRL.

MAIN POINTS OF OPERATIONS.	CONDITIONS BEFORE OPERATIONS.	OBJECTIVE CONDITIONS AFTER OPERATIONS.	SUBJECTIVE FUNCTIONAL RESULTS.
Tibialis anticus tendon transplanted into external cuneiform bone. Cuneiform osteotomy of neck of stragalus. Lengthening of tendo Achillis.	Moderate equinus and moderate varus position. Peroneal group of muscles weak. Good power in tibialis anticus and in tendo Achillis group. No apparatus worn. Duration of paralysis, ten years.	Eight years and one month after operation the foot is slightly undercorrected in weight-bearing position, and slightly more so without weight. Stability excellent. Voluntary and passive dorsal flexion of 75°-80°. No abduction but free adduction. Transplanted tibialis anticus actively functioning. Tendo Achillis group of moderate strength. Brace is now necessary.	She would go through the experience again for the benefit derived from the improved position and function of the foot.

No. 7. ELEVEN-YEAR OLD BOY.

Tibialis anticus tendon transplanted into cuneiform osteotomy line of external cuneiform bone.	Considerable varus deformity with adduction of forefoot. Slight equinus. Walks on outer edge of foot and ends of extended toes. Operation advised after previous ether manipulations. No brace worn. Duration of paralysis, many years.	Five years and one month after operation the foot is considerably undercorrected. Dorsal flexion limited passively to slightly less than a right angle. Calluses still present on anterior out part of foot. Slight function in transplanted muscle. No brace worn.	Patient thinks the surgical operation was some benefit, that there is some improvement in position of the foot.
--	--	--	---

No. 8. THIRTEEN-YEAR OLD BOY.

Peroneus longus tendon transplanted through the interosseous membrane into arthrodesis line between astragalus and scaphoid bones. (Fasciotomy of fascia lata below anterior superior iliac spine, followed two months afterward by open reduction of dislocated hip.)	Foot was useless and held in a valgus position. Patient walked with crutches. Hip dislocated. Thigh contracted in flexed position of twenty degrees. Some muscular function in iliopectas, glutei and hamstring muscles; also in peroneal group, tendo Achillis and in extensor longus pollicis. Duration of paralysis, twelve years.	Six years and two months after operation the foot is held in fairly good position by the foot plate of a long leg brace. Still some lack of correction of original deformity. Passive motion possible to a right angle, and dorsal flexion voluntarily is distinctly increased through function of the transplanted muscle. Still uses crutches.	Patient thinks the foot is very much more useful because he can bear some weight upon it and avoid so much weight on crutches.
--	--	---	--

No. 9. TWELVE-YEAR OLD BOY.

Peroneus longus tendon transplanted into arthrodesis line between astragalus and scaphoid bone, passing through interosseous membrane and under annular ligament.	Moderate valgus deformity. Tibialis anticus muscle weak and tendo Achillis group less so. Peroneal group of muscles and extensor communis digitorum strong. No brace worn. Duration of paralysis, nine years.	Five years and one month after operation he reports by letter, that the foot is still undercorrected and probably will require a brace before long although none is used now. There is a tendency for the valgus deformity to return, but he states that he has a little more voluntary motion in the foot than previously.	He thinks the operation a little improvement.
---	--	---	---

No. 10. EIGHTEEN-YEAR OLD BOY.

MAIN POINTS OF OPERATIONS.	CONDITIONS BEFORE OPERATIONS.	OBJECTIVE CONDITIONS AFTER OPERATIONS.	SUBJECTIVE FUNCTIONAL RESULTS.
Extensor longus hallucis tendon transplanted into head of first metatarsal bone. Fasciotomy of plantar fascia. Lengthening of tendo Achillis.	Moderate equinus and slight varus. Hyperextension of great toe. Abductors of foot were weak. Plantar fascia contracted. Tendo Achillis shortened. No brace worn. Duration of paralysis since babyhood.	Four years after operation the foot is still somewhat undercorrected. Cavus and contracture of tendo Achillis persist in lessened degree. Dorsal flexion to a right angle is impossible, and patient walks on heads of metatarsals more squarely than previously. Calluses present in diminished degree. Hyperextension of great toe lessened but not perfectly corrected. No apparatus worn. He returned to the hospital after discharge from the ward, and the cast was removed, then he disappeared entirely. This fact probably has bearing upon the degree of improvement finally shown.	Patient says the foot appears straighter to him and walking has been improved.

No. 11. TWENTY-YEAR OLD WOMAN.

Extensor longus hallucis tendon transplanted into head of first metatarsal bone. Tenotomy of tendo Achillis.	Some equinus deformity and great toe hyperextended. Tibialis anticus and extensor communis digitorum muscles are somewhat weakened. No apparatus worn. Duration of deformity, eighteen years.	Two years and three months after operation the foot shows nearly perfect correction of equinus deformity and undercorrection of the great toe defect. Voluntary motion is possible to a right angle in dorsal flexion. The transplanted tendon of extensor longus hallucis functions only slightly. A foot plate is worn.	She is much pleased because she is able now to walk any distance desired without discomfort. The foot is in much more serviceable position with contractures of tendo Achillis completely relieved.
--	---	---	---

No. 12. FIFTEEN-YEAR OLD GIRL.

Extensor longus hallucis tendon transplanted into head of first metatarsal bone. Arthrodesis of first phalangeal joint of great toe. Tenotomy of tendo Achillis. Plantar fasciotomy.	Marked equinus position. Great toe hyperextended and flexed. Extensor of great toe weakened. Tendo Achillis of good strength. Dorsal flexors of foot weakened but not paralyzed. No apparatus worn. Duration of paralysis since babyhood.	Two years and nine months after operation the foot is somewhat undercorrected for equinus deformity. Some calluses are still present under heads of metatarsal bones. Voluntary and passive motions in dorsal flexion are stopped apparently by bony obstruction at 80°. Extensor longus hallucis tendon is functioning well in its transplanted position. Slight voluntary adduction and complete voluntary abduction of the foot are possible. No apparatus worn.	Patient says there has been an improvement in her walking after operation.
--	---	---	--

No. 13. FOUR AND A HALF-YEAR OLD GIRL.

MAIN POINTS OF OPERATIONS.	CONDITIONS BEFORE OPERATIONS.	OBJECTIVE CONDITIONS AFTER OPERATIONS.	SUBJECTIVE FUNCTIONAL RESULTS.
Peroneus tertius tendon transplanted into periosteum of scaphoid bone. Silk ligament passed from tibia to tarsal bones at inner side of foot.	Marked valgus deformity. Tendo Achillis group of muscles, peroneal muscles and extensor communis digitorum are fairly strong. Tibialis anticus, extensor longus hallucis and tibialis posticus are weak. Valgus brace worn. Duration of deformity, three years.	Seven years and one month after operation the foot is held in practically perfect weight-bearing position. Silk ligament strong and functioning well. Slight function in transplanted tendon. No voluntary dorsal flexion but passive motion dorsally to a right angle. No brace needed.	Patient's mother thinks the foot has been greatly improved, that there has been much improvement in form, stability and usefulness.

No. 14. NINE-YEAR OLD BOY.

Tibialis posticus tendon transplanted through interosseous membrane under annular ligament into arthrodesis line between os calcis and cuboid bone. At second operation extensor longus hallucis tendon transplanted into head of first metatarsal bone.	Moderate varus deformity resulted from previous surgical efforts to correct valgus deformity. The patient had been operated upon originally in another state and his valgus deformity considerably overcorrected. An attempt was made then to compensate for the varus position by a second operation of transplanting the tibialis anticus tendon into the external cuneiform bone. Varus position still persisted and the patient was walking with crutches with his foot held in a plaster when admitted to the orthopedic ward of the Massachusetts General Hospital. Duration of paralysis, several years.	Seven years and two months after operation the patient reports by letter that he can use his foot better and does not wear a brace. In walking the foot slaps down rather hard, and there is apparently some hyperextension and flexion of the great toe.	The patient thanks the doctors in the letter for all that was done. Presumably the last two operations represent a partial correction of deformity with a more serviceable foot.
---	--	---	--

No. 15. THIRTEEN-YEAR OLD GIRL.

Tibialis posticus and peroneus tertius tendons transplanted into tendo Achillis. Transverse osteotomy of os calcis and elevation of its posterior fragment for reunion in corrected position.	Moderate calcaneus deformity with pes cavus. Slight power in all lower leg muscles. Tendo Achillis group weak. Partial paralysis of quadriceps and biceps muscles in thigh. No brace worn. Duration of paralysis, seven years.	Four years and eight months after operation the foot is still in calcaneus and cavus position of less degree. Position in weight bearing is good but more unstable. Some strength in tendo Achillis. No brace worn although one has been tried unsuccessfully.	Patient states that she turns her foot more than she did before operation, and thinks the condition is worse. From an anatomical standpoint there has been some improvement in form at the loss of the more important feature, functional stability. An unsuccessful result.
---	---	--	---

No. 16. FOURTEEN-YEAR OLD BOY.

Arthrodesis of ankle joint preceded two months, by plantar fasciotomy and arthrodesis of astragalo-scapoid joint.	Varus position with considerable cavus deformity. Walked with brace and high soled shoe. Muscles of lower leg badly paralyzed including tendo Achillis group, peroneals, extensor communis digitorum and tibialis posticus. Duration of paralysis, since babyhood.	Five years and three months after operation a friend reports that the foot is all right. "A great success." Patient considered one of the finest dancers in town. On leaving the hospital he returned twice to the out-patient department, was fitted with a brace and then disappeared seven weeks from time of operation.	An improvement from the patient's standpoint.
---	---	--	---

No. 17. TWENTY-ONE-YEAR OLD MAN.

MAIN POINTS OF OPERATIONS.	CONDITIONS BEFORE OPERATIONS.	OBJECTIVE CONDITIONS AFTER OPERATIONS.	SUBJECTIVE FUNCTIONAL RESULTS.
Arthrodesis of ankle joint. Tenotomy of peroneal tendons.	Valgus deformity. No power in leg muscles except slight function in peroneal group and in extensor communis digitorum. Valgus foot brace worn. Duration of paralysis, eighteen years.	Six years and four months after operation the foot is held in excellent weight-bearing position with practically no motion in the ankle joint. There is still a little cavus deformity. No apparatus needed.	The patient is pleased with the result, and there has been marked improvement in usefulness of the foot from improved position and stability.

No. 18. SEVENTEEN-YEAR OLD BOY.

Arthrodesis of ankle joint. Arthrodesis of astragalo-scapoid joint. Peroneus tertius tendon transplanted into scaphoid bone.	Marked valgus deformity. Anterior part of the foot abducted. Lower leg muscles all weak. Tibialis anticus and tibialis posticus muscles weakest. Peroneal group strongest. Tendo Achillis group and extensor communis digitorum intermediate in strength. Walked with crutches and very little weight bearing on affected foot. Duration of paralysis, since babyhood.	Seven years and three months after operation the patient reports by letter that his foot turns in as badly as before operation. He used crutches for six years then his local shoemaker made him a shoe which he uses with a brace and a cane. He returned twice to the out-patient department where he was fitted with a brace, after which he was lost sight of entirely six weeks after operation.	He says the operation did him no good, although he is no worse off apparently. Lack of supervision and of post-operative care seem important factors in the late results of this case.
--	--	---	--

No. 19. TWENTY-NINE-YEAR OLD WOMAN.

Arthrodesis of the ankle joint. Fracture of lower end of fibula.	Valgus deformity. Stability of foot poor. No power in anterior tibial muscle or peroneal group. Tendo Achillis group weak, also quadriceps weak in thigh. Valgus foot brace worn. Duration of paralysis, many years.	Five years and two months after operation there is firm union in the ankle joint with a little voluntary and passive motion at medio-tarsal joint. Stability and weight-bearing position are excellent. A little cavus deformity persists. Wears a plate.	She thinks the operation a great benefit, and has not missed a day's work for four years. From an orthopedic standpoint the result is excellent.
--	--	---	--

No. 20. THIRTY-TWO-YEAR OLD MAN.

Arthrodesis of ankle joint preceded five weeks by operation, plantar fasciotomy, division of calcaneo-scapoid ligament and osteotomy of astragalus. (Jones' operation in two stages.)	Valgus position. Cavus deformity. Valgus foot brace worn. Lower leg muscles all practically paralyzed. Duration of paralysis, many years.	Four years and eight months after operation the foot is in good right angled weight-bearing position with ten or fifteen degrees of passive motion. Some persistent cavus. A few degrees of adduction and abduction passively are possible. No brace needed. He remained under hospital supervision only five months, being fitted with a brace, and then he disappeared, walking satisfactorily without crutches.	A decided improvement from patient's standpoint.
---	---	--	--

No. 21. TWENTY-YEAR OLD WOMAN.

MAIN POINTS OF OPERATIONS.	CONDITIONS BEFORE OPERATIONS.	OBJECTIVE CONDITIONS AFTER OPERATIONS.	SUBJECTIVE FUNCTIONAL RESULTS.
Three operations. An orthrodesis of left ankle joint was followed in one week by an astragalectomy in the right foot. The third operation an astragalectomy, with transplantation of peroneal tendons into tendo Achillis, followed the orthrodesis of the left ankle in eight months, and was performed on account of increasing motion and valgus deformity following the first operation.	Extensive paralysis of both legs. Double leg braces worn. All muscles except tendo Achillis group were paralyzed on the right side. All muscles except intrinsic muscles of the foot were nearly paralyzed on the left side. Slight power in peroneal group. Hamstrings and quadriceps active in right thigh. Hamstrings weak and quadriceps fairly active in left thigh. Duration of paralysis, since eight months of age.	Three years and one month after operation she can walk around the house without any apparatus. Awkward slow gait due to genu valgum. Both feet are in good weight-bearing positions with good stability. Passive motions of thirty or forty degrees are possible. Right tendo Achillis fairly strong. Left tendo Achillis weak but functioning.	Patient considers the operation a great success because she is no longer obliged to wear braces, and is able to get around comfortably although somewhat awkwardly.

No. 22. THIRTY-EIGHT-YEAR OLD WOMAN.

Astragalectomy. Transplantation of peroneus longus and peroneus brevis tendons into tendo Achillis. Peroneus tertius transplanted into tibialis anticus tendon.	Calcaneo valgus position. Instability in weight bearing. Tendo Achillis group weak. Tibialis anticus paralyzed. Peroneal muscles strong. Foot brace worn. Duration of paralysis, since childhood.	Two years and three months after operation the foot is in much improved weight-bearing position. Fifteen degrees of passive motion at the ankle, and a few degrees of voluntary motion from the transplanted peroneus tertius. Tendo Achillis fairly strong. Still some instability in foot, but this is not noticed very much because a long leg splint with foot plate has to be worn on account of a weak knee.	She thinks the operation a benefit, although obliged to wear more apparatus now, because she can walk better on the foot. The foot is more serviceable from having an improved position.
---	--	--	---

No. 23. FIVE-YEAR OLD GIRL.

Astragalectomy. Transplantation of peroneus longus and peroneus brevis tendons into tendo Achillis.	Calcaneo valgus position. Lower leg muscles all weak. strongest ones are peroneal muscles and extensor longus hallucis. No brace worn. Duration of paralysis, since birth.	Two years and six weeks after operation the foot is in excellent position with good stability. Passive motion of fifteen or twenty degrees. Slight but useful function in tendo Achillis, also very slight function in anterior tibial and extensor communis digitorum tendons. No brace needed. She disappeared two months and three weeks after operation when the cast was removed.	Much improvement from patient's standpoint.
---	---	---	---

No. 24. TWELVE-YEAR OLD GIRL.

Astragalectomy. Tenotomy of peroneal tendons.	Marked varus deformity. All muscles of lower leg very weak. Duration of paralysis, six years.	Two years and eleven months after operation the foot is slightly overcorrected into a little valgus. Good stability in weight-bearing. A few degrees of passive motions at the ankle are possible. No voluntary motion of the foot. Wears a long leg splint on account of weakness of knee.	She thinks the operation did some good, for in spite of more apparatus worn it seems that the leg is more useful.
---	--	---	---

No. 25. SIXTEEN-YEAR OLD GIRL.

MAIN POINTS OF OPERATIONS.	CONDITIONS BEFORE OPERATIONS.	OBJECTIVE CONDITIONS AFTER OPERATIONS.	SUBJECTIVE FUNCTIONAL RESULTS.
Astragalectomy. Two years later extensor longus hallucis tendon was transplanted to head of first metatarsal bone, and first phalangeal joint of great toe stiffened.	Moderate valgus deformity. All lower leg muscles weak. Moderate hyperextension of great toe. Hip dislocated. Quadriceps partly affected in thigh. No brace worn. Duration of paralysis, since babyhood.	Six years after her first operation the foot shows a good position but is rather unsteady in weight-bearing. There are a few degrees of passive motion at the ankle. The position of the toe has been improved, but some motion in first phalangeal joint of toe still exists. No braces worn.	Patient says she is worse than before operation because of the instability of the foot.

No. 26. FOURTEEN-YEAR OLD GIRL.

Astragalectomy. Peroneus longus tendon transplanted into tibialis anticus tendon.	Calcaneo-valgus deformity. Tibialis anticus paralyzed. Tendo Achillis group weak. Peroneals fairly strong. Some cavus deformity. Wore leather ankle support.	Four years and five months after operation the foot is in good weight-bearing position, slight valgus with arch well preserved, good stability. Voluntary dorsal flexion is possible through a few degrees. Tendo Achillis of fair strength. Passive motion to right angle dorsally, also moderate adduction and abduction. Wears a leather ankle support.	Considerable improvement from patient's standpoint.
Peroneus brevis and tertius tendons transplanted into tendo Achillis.	Duration of paralysis, twelve years.		

THE CARNIVOROUS AND HERBIVOROUS TYPES IN MAN: THE POSSIBILITY AND UTILITY OF THEIR RECOGNITION.

II. CERTAIN GENERAL CONSIDERATIONS.

By JOHN BRYANT, M.D., BOSTON.

INTRODUCTION.

THE proposition of the carnivorous and herbivorous types in man, as presented in a recent number of this JOURNAL,¹ has met with numerous expressions of interest in various quarters. Being, however, somewhat new, it is doubtless not to be wondered at, that although the basic idea appears to have created a favorable impression, the utility or even the possibility of applying the theory to the actual conditions of practice has remained in doubt. Therefore it is desired to submit a few general observations bearing upon this phase of the question, before considering in detail the set of tables given in the first paper of this series.

The editor of the JOURNAL, in a very sympathetic discussion² of this first paper, mentioned the diatheses, considered certain aspects in the evolution of the types, their characteristics, and referred to possible underlying sex differences.

The writer is in entire agreement with the editor's discussion of these points, which will be re-

viewed and perhaps extended, and then an attempt will be made to show a few angles at which the type theory comes into close contact with actual every day life; angles at which it is believed that the application of the theory will prove of service as a distinct aid in the obtaining of practical results—for example, by the educator, the employer of labor, the life insurance actuary, and the doctor.

DIATHESSES.

In his remarks upon the "Regulators of Metabolism," Paton³ has grouped the three chief influences concerned, in the following concise manner:—

1. Hereditary Inertia or Inherited Developmental Tendencies.

2. The Nervous System.

3. The Chemical Products of Various Organs, the So-called Internal Secretions.

Of these three factors the third doubtless comes to occupy the most prominent place in post-embryonic or certainly in adult life. Thus the various diatheses which have been described ultimately represent the outward manifestations of the vagaries of the ductless glands. There is some evidence to show that within limits the activities of these glands may be varied by persistent attention to diet, but if one recalls the rather constant differences in the ductless gland supply of the two types it will not be difficult to prophesy in which group a given diathesis will

fall: thus exophthalmic goitre suggests the carnivorous, and myxedema the herbivorous type.

EVOLUTION.

Treves⁴ studied evolution in 200 different species of animals, as illustrated by changes in the intestinal canal; he concluded that evolution of the animal species largely depended upon food environment, and that although a gut might acquire specialized characteristics, these were easy to recognize, while the rudimentary character of a given gut remained very constant. Upon the strength of this work, he stated that the carnivore, with its short simple intestine, can be traced back by way of the felines, the canines, the bears and the raccoon, through the insects and cheiroptera, to the amphibians and the monotremes, among the latter of which one finds the echidna, and still lower the ornithorhynchus. The herbivore, on the other hand, has an entirely different intestinal ancestry, leading back by way of the rhinoceros, the tapir and the horse, the hog, the hippopotamus and the ruminants, through the ungulates to the rodents and the marsupials. There is no overlapping. These two main groups run parallel and distinct, and are themselves distinct from a third group composed of the edentata which, from the evolutionary point of view, leads nowhere: its ancestors are extinct.

In the human also it seems that the statement of Treves concerning the dependence of type upon food environment must hold good. For example, many observers have demonstrated that within a given species of animal intestinal length is dependent upon the digestibility of the ingested food. But back of such lesser variants one finds active the restrictions imposed by climatic conditions. Thus temperature controls not only food distribution, but growth and differentiation, since these two are incompatibles. At the equator light and heat are intense; plant growth is abundant, but human growth is stopped by early differentiation and maturity. In the temperate zone toward the cold area, conditions are optimum for human growth, but plant growth is less luxuriant. In the arctic regions, with a minimum of both light and heat, human growth is again stunted, and plant growth is conspicuous by its absence. As plant growth decreases with the distance from the equator, so, conversely, man's food becomes more and more carnivorous the nearer he lives to the arctic zone; in these regions he must eat flesh or starve. On account of these and other factors it comes about that man at the equator eats a high carbohydrate diet, the dweller in the temperate zone uses a mixed diet, and the arctic yields a pure meat with high fat diet. It is only reasonable to suppose that this also must have its effect upon development. Doubtless it is for some of these reasons, as well as on account of the higher proteid diet, that the children of the immigrant from Southern Europe tend toward the carnivorous type in our northern states.

Arguing somewhat after this manner, Cattell⁵ has asserted that a boy born in Massachusetts or in Connecticut is fifty times as likely to become a scientific man as a boy born along the southeast seaboard, from Georgia to Louisiana—that is, if he stays put. Somewhat similar ideas are advanced by Ellsworth Huntington,⁶ in an article entitled "Is Civilization Determined by Climate?" He draws attention to the results of bringing the negro north and of bringing the white man south in America, as indicating an inversion of hereditary ability by climate. Huntington recognizes only five centres of high civilization and climatic energy (variability) at the present day: Western Europe, Northeastern United States, Japan, the Pacific Coast of the United States, and Southeastern Australia including New Zealand. He holds that the decline of ancient civilizations, such as those of Mesopotamia, India, and China, was synchronous with climatic alterations. When one keeps in mind these statements, and the fact of the retrogression of the glacial border line during the past ages, it is perhaps interesting if not profitable, to speculate on the northward march of power in Europe. First Egypt, then Rome, Spain and France held the sceptre. Now it is England. After England, then what, and when?

TYPE CHARACTERISTICS.

Given the presence of the two human types in one locality, what may be expected of them? History provides abundant answer. Thus in England the square-jawed Roundheads under Cromwell stirred up the country for a few years and disappeared. The hatchet-faced Puritans found England too crowded and settled a new world. Today hawk-nosed bird-men rule the upper air. The carnivore is the restless pioneer, inductive, dying ever on the outskirts in search of something new.

The herbivore is the sedentary stabilizer, deductive, ever at his appointed task. Both are necessary to the progress of the world, and neither can do the work of the other. It seems unlikely that the human species will ever be reduced to one type, but should this come to pass one might hazard a surmise that the surviving type would be a mixed one, perhaps three parts carnivore and one part herbivore.

SEX AND TYPE.

There can be no question but that in the human species the female tends more to the herbivorous and the male toward the carnivorous type. Doubtless, as among the American Indians the influence of the chase and of the meat diet worked in one direction in the men, and the sedentary habits, hard muscular work, and carbohydrate diet of the squaws was active in the other direction: meat and the wilderness, civilization and cereals, are still in a sense synonymous. But there is another and no less potent factor, yet active. This is the demand of pregnancy and

lactation upon the calcium metabolism of the woman. Under present conditions meat for the table is carefully drained of most of its calcium before it leaves the slaughter house. This is proved by the fact that it has been possible for numerous workers to produce a calcium deficiency in laboratory animals by the simple process of feeding them unlimited quantities of meat, corn, and fat. Consequently if a woman is to get an adequate calcium supply for the period in question she must get it from vegetables, from an herbivorous diet, and it is possibly for this reason that many women instinctively crave a calcium-high carbohydrate diet during pregnancy. For this reason then, if for no other, it would seem that woman must ever remain at least predominantly herbivorous, in spite of her very evident present tendency toward the male type. This tendency also doubtless depends on the fact that increasing prosperity results in increasing proteids, especially meat, in the diet, a phenomenon now evident not only in this country, but all over Europe, and in Germany in particular, where per capita meat consumption has doubled in recent years.

The carnivore is dominant among the lower animals, and among men today unless royalty and nobility are now effete, but for the good of the race it is to be hoped that women do not aspire too seriously to join the dominant group.

THE EDUCATOR.

Being concerned mostly with children in the adolescent formative stage, the constructive opportunities of the educator loom large, and a knowledge of type puts at his disposal a means of insight into the mental and physical makeup of his pupil which can in no other way be so easily acquired; the possibilities for helpfulness and prevention are almost limitless. Environment is doubtless important, but it must after all be considered as affecting different material in different ways, and short fat John Johnson will under a given stimulus react in an absolutely different manner from lanky overgrown James Jamieson. Here is a new boy. What is he and how will he act and for what will he be best prepared? Simple anthropometric measurements at once determine whether he is of an extreme or an intermediate type. If he is of intermediate type, a medical examination, with perhaps a thorough Roentgenographic study of the gastrointestinal tract will further aid classification. This accomplished, all else within reasonable limits of error and with only sufficient exceptions to prove the rule, may in a broad way be predicted. The physical and the mental education may be directed into the proper channels, and the working boy may be prepared for a definite occupation with full assurance that it will be one in which he will appear to good advantage. There is also a possibility that when an extreme type is recognized early, persistent attention to diet over years of time may produce some modification of type in a given individual.

should this be thought desirable. In a word, a study of type is one more aid to efficiency.

THE EMPLOYER OF LABOR.

The man and the job: will they fit each other? Some such question is ever presenting itself in one form or another to the employer or his subordinates. How is one to tell? The expert knows at a glance perhaps. Ask him how he knows, and it is doubtful if he can go much further than to say that his judgment is based on experience. Type provides another key, should experience be scanty.

A large employer of labor in one of the government services was discussing type with me. He found the subject interesting, for long experience had enabled him to divide labor into two classes. Being asked on one occasion by the chief of service how much help he wanted for a certain piece of work, he replied without thinking how it would sound to his chief, "about so many broad-backs and so many narrow-backs." Under the circumstances this remark necessitated apology and explanation, but in it lies a nut-shell compend of the relation of labor to type. The explanation was to the effect that the broad-backs were the office force, who stayed behind and worked up the data obtained by the narrow-backs; the latter were to draw their pay for their proficiency in overcoming obstacles to success in field work.

THE LIFE INSURANCE ACTUARY.

The actuary now attributes great importance to blood pressure; it is precisely on this question of blood pressure that knowledge of type may be of use to the actuary, since it is one of the most characteristic points of difference between the two types. Assuming that the normal pressure ranges from about 110 to 140 (systolic) in healthy adults, this range of 30 m.m. may be split in half at 125. The carnivore will usually be found to have a pressure below, and the herbivore above this figure. Therefore a reading of 95 or of 155 must be interpreted according to type. In disease, pressure tends to fall in the carnivore but to rise in the herbivore. Conversely, high pressure is more suggestive of serious trouble in the carnivore, and low pressure in the herbivore. In other words, a pressure of 155, which may be said to be 15 m.m. above the upper normal limit, is so only for the herbivore; for the carnivore it is an increase of 30 m.m., or 100% more serious an indication than for the other type, corresponding to a reading of 170 for the herbivore. The same argument applies to the reading of 95; it is only 15 m.m. low for the carnivore, but 30 m.m. low for the herbivore, corresponding to a drop to 80 m.m. in the carnivore.

A further illustration of the importance of considering type is provided by the way in which certain drugs produce a given action in this person, but its contrary in another person. This

is entirely paralleled in work upon the lower animals, as for instance by the finding of Dale and Laidlaw,⁷ that beta-aminazolyethylamine* produces a large vaso-dilator fall of blood pressure in carnivora, but a vaso-constrictor rise of pressure in the rabbit. It is thus obvious that type provides the actuary with an additional means of calculating the risks he is called upon to insure.

THE DOCTOR.

The set of tables recently presented¹ makes it unnecessary to discuss at length the value of a knowledge of type to the medical man, especially in view of the publication in this JOURNAL of the recent Shattuck Lecture by Dr. Joel E. Goldthwait,⁵ who has in his essay presented a valuable summary of present knowledge of type, the results of his own observations and those of others, under the title "An Anatomic and Mechanistic Conception of Disease." To this article and to the editorial⁹ accompanying it, those interested are referred, with the assurance that they will be convinced on at least two points—that present conscious medical appreciation of type only follows upon some thousands of years of unconscious appreciation of type by the non-medical world, and that the chief lesson to be learned is concerning the value of education upon this subject.

The laboratory worker who conducts his investigations without regard to type leaves them open to criticism. Thus metabolism experiments must be conducted upon individuals of the same type or the subjects will react differently to a given diet. Doubtless in this fact lies a possible suggestion for the solution of certain discrepancies reported by various laboratories working upon a given problem.

Appendicitis has for some years been used as a touchstone for any proper medical discussion. One has to look no further to find a means of illustrating the value of applying type to clinical medicine. The carnivore may have a chronic appendix for years, but the chances are more than ten to one that it will not kill him. It may be said in parenthesis that in him the appendix gets a bad name when it is usually at fault only secondarily to trouble in the region of the hepatic flexure, or because, for instance, the splenic flexure is very high and difficult of passage for ingested food. If, on the other hand, the herbivore ever gets appendicitis, it is likely to be primary, fulminating, and apt to flood the peritoneum with pus, and to cause sudden death. There is nothing mysterious in this difference of the disease in the two types. It is to be expected; it is the natural result of rather constant anatomical differences in the shape of the appendix. The appendix in the carnivore is conical in outline, and the base of the cone is always at the orifice of its lumen, making obstruction improbable. The herbivore, on the other hand, is the unfortunate possessor of an

appendix shaped more like a tube with end blind and sides parallel. Its diameter is as great at the tip as at the orifice, unfortunately often greater. There is even a tendency to stricture at the orifice, with results which are only too obvious. Thus it comes about that this type of appendix not infrequently acts as an efficient closed tube for the cultivation of trouble in the form of bacteria. In this connection it may be observed that in a somewhat extensive series of autopsies studied in Europe,² it was without exception the perfectly developed, beautifully modelled herbivorous type of child which died of fulminating appendicitis; the scrawny children died of other things, but not of trouble primary in the appendix.

CONCLUSION.

The theory of type can and should be applied to the conditions of practice. Knowledge of the meaning of type is an asset valuable to the practitioner in every field of human endeavor.

PNEUMOCOCCIC ARTHRITIS, WITH REPORT OF SIX CASES.

BY JAMES WARREN SEVER, M.D., BOSTON.

Junior Visiting Surgeon, Children's Hospital, Boston; Surgeon to The House of the Good Samaritan.

[From the Orthopedic Department of The Children's Hospital, Boston.]

PNEUMOCOCCIC arthritis is a condition which usually occurs during the course of a pneumonia, and is relatively infrequent. It generally appears during the first nine days of a pneumonia, but may come on at a later period. Primary pneumococcic arthritis attacks are rare. Severe arthritis may follow a mild pneumonia.

Occurrence. Arthritis occurs in about 0.1% of pneumonias. Strickler, quoted by Richardson,¹ has noted that out of 11,846 cases of pneumonia, arthritis occurred 800 times, or 14%, which is unusually high. Herrick, on the other hand, has reported that it occurred but 14 times in 11,706 cases of pneumonia in foreign clinics, or one case to every 800 of pneumonia, which it may be stated is about the usual percentage of occurrence. It may occur at any age, is apt to be more frequent in the first ten years of life, and is seen more often in the male than in the female.

Primary joint infections are more common in

* The amine from histidine commonly called histamine or ergamine.

children than in adults, and previous damage to the joint by trauma and rheumatism predispose to infection. Alcoholics are particularly prone to infection.

Up to 1911 there had been reported but 172 cases of pneumococcal arthritis, showing that it is a relatively rare condition. The first case where the organism was isolated and identified was reported in 1888 by Weichselbaum. Buckley² states that 34% of the 172 cases collected by him occurred in the first five years of life. Herzog³ states that joints of children in early life are predisposed to pneumococcal infection the same as other serous membranes, that is, pleura, peritoneum, pericardium and meninges. It is more apt to be rare in adults without a preceding lung infection.

Herzog believes that the frequency of infectious arthritis in infants is due to the structure and vascular arrangements of the bony portion of the joints. He quotes Neumann, who has shown that the capillaries of the bone marrow in infants are of a larger calibre than the smallest arteries, an arrangement whereby the blood current is rendered extremely slow and the deposition of infective organisms in the tissues favored.

Scr. Buckley reports that in an analysis of his collected cases over ten years of age he found approximately 78% males and 22% females. This disproportion has usually been ascribed to the influence of trauma, which unquestionably predisposes to infection, and to which the male is more subject than the female. In the six cases, five children and one adult, I am going to report, there were two males and four females. The question of trauma does not hold true to such an extent in children under ten, and the predominance of the male sex is not shown in a study of cases occurring in the first decade or semi-decade.

Period of Onset. Buckley states that in 73 cases in his series eleven days was the average time elapsing between the onset of the pneumonia and the development of the arthritis. In this series of six cases of mine the first case developed three weeks after a tooth extraction; the second five days after a primary trauma of the knee joint, with no pneumonia at any time; the third had pneumonia five weeks before, and double otitis media three weeks before knee involvement; the fourth was an adult, an elderly man, who developed a suppurative shoulder nine days after the onset of his pneumonia, and following a trauma to his shoulder the day before the onset of his pneumonia, during the clearing up of an unresolved condition of consolidation in his lungs; the fifth had had several attacks of broncho-pneumonia covering a period of years, and the knee became involved five days after an acute attack of otitis media; the sixth had had an attack of pneumonia two weeks before the onset of the knee symptoms.

In this series it can be seen that the knee was involved five times and the shoulder once. This is true of all series reported, the knee being the most frequently involved, with the shoulder next

in frequency. The other large joints follow, such as the elbow, hip, ankle and wrist. Trauma, previous joint disease and diminished local resistance are adequate causes for local infection, for it has been shown by Rosenow and Cassati that the pneumococcus is usually found in the blood of a person suffering from a pneumonia. In regard to the cases which had had no previous pneumonia, but whose infection was secondary to some local infection, such as a tooth abscess or an otitis media, it can be stated that many otitides mediae in children are due to the pneumococcus, and that pneumococci may always be found present in an individual's mouth.

The process is usually suppurative, but in a few cases may be serous.

There may be three forms of such joint involvement, namely: (1) light, without visible changes, (2) serous form, (3) purulent form, which is the most common. There may also be periarticular conditions with secondary joint involvement. The cases appearing during the course of a pneumonia are said to be much more severe than those appearing later. The mortality has been quoted all the way from 75% (Zezas⁴) to slightly over 50% (Buckley). Herzog states that the mortality in infants is about 39%. In regard to children, the end results are usually good as far as the joint is concerned.

Forms 1 and 2, as noted above, may get well without other treatment than simple fixation, and rarely require more than that, except possibly aspiration. Provided free drainage is established where pus is present there is usually very little permanent damage done to a joint in children. Given free drainage the pus ceases to spread in any direction, and the affection is generally sharply localized.

The prognosis is usually good, provided the drainage is satisfactory and the infection has occurred after the pneumonia has cleared up. Certain cases are so overwhelmed by the infection, however, that they die in spite of adequate drainage. Ankylosis of the joint is rare.

Clinical Symptoms. Clinically the condition is recognized by the ordinary signs of an acute inflammation, and if following or during an attack of pneumonia the diagnosis is reasonably clear. The actual diagnosis, however, depends on bacteriological examination. Infection of a joint may occur during the course of a pneumonia, which, however, is not necessarily pneumococcal in origin, and a careful bacteriological examination is necessary to establish a diagnosis. The joint is swollen, tender, not reddened, sensitive to motion and to pressure. There is also an irregular or high temperature, which usually drops by crisis following evacuation of the pus.

Treatment. The joint may be aspirated to determine the presence or absence of pus and to determine the bacteriological contents, following which, if pus is present and the symptoms persist, there should be an open incision and free drainage. In children wholesale opening of the joint with curetting, or opening of the shaft of the

bone should not be practiced, for these measures do more harm than good, and tend to spread the infection and increase the destructive process.

Following operation, fixation of the part by a splint or a plaster shell until the wound has ceased to discharge is essential.

Bacteriology. Attempts have been made in two of these cases to be reported to differentiate the types of pneumococcus in accordance with those described by Cole,⁵ but we were unable to produce the pneumococci in pure cultures by means of passing them through mice, even when we used emulsions of the affected lungs or pus from the knee joint.

In detail the following six cases are reported:

CASE 1. J. C. Boy, age 4. Children's Hospital, January 11, 1908. Three weeks before entrance child had a tooth pulled. Two days following this the cheek swelled and has remained swollen. During this time he was up and about playing, although he seemed feverish at times. On January 1, 1908, eleven days before entrance, the child got up as usual, but at noon the father noticed that he was lame. The child kept putting his hand down on to his right thigh. At first the knee was swollen, this later disappeared, and the thigh above became more swollen. Has been in bed for past ten days. Three days ago, there appeared a swelling on the right side of the face over the region of the parotid gland. The father thinks that the child breathes faster the past three or four days, and has had a slight cough for several days.

Physical examination showed a child, well developed and poorly nourished, dusky pale color, cervical glands enlarged, over carotid on right there is a tender, warm, fluctuating and reddened area, bloody nasal discharge, pharynx reddened, looks raw, one shallow ulcerated area size of a split pea between right anterior pillar and uvula. Breathing rapid and shallow, lungs show diminished resonance, and typical pneumonic areas over whole of both lungs. Extremities—Right leg flexed at hip to about 50 degrees, cannot move leg. Right thigh swollen, markedly so in its inner and posterior aspect, and rather fusiform in shape. Very tender, marked fluctuation, no apparent involvement of hip joint, slight general icterus.

Operation with gas. Incision over area of greatest fluctuation on thigh and about eight ounces of foul, yellowish-green pus evacuated, rather thick. Culture showed pure pneumococcus. The next day, the 12th, he was given 3000 units of anti-pneumococcus serum without benefit. The 13th both ears began to discharge, and there was increasing delirium, with coma, twitching of right arm, retraction of head, etc. The day following, the 14th, he died. There was no autopsy, but cultures from the throat, the thigh abscess and from the blood showed pure pneumococcus. There was no x-ray of the thigh taken, for the child was too sick to be moved.

Case 2. A. K. Girl, age 15 months. Five days before entrance the child, while walking on the floor, slipped and fell, striking her knee. The next day she could not walk, and has not been able to since. Four days ago the knee began to swell. Motion of the knee causes pain.

Physical Examination. Fat, well-developed baby, breast-fed. Right leg normal. The left leg was held

flexed at about 45 degrees, and there was considerable pain on attempts at motion. All the normal landmarks about the knee were obliterated. The surface temperature was markedly increased, with considerable capsular thickening. The patella was movable.

The child was kept quiet, but the temperature kept up to about 103, so the joint was aspirated on the second day after admission. Examination of the fluid aspirated showed the pneumococcus in pure culture. The day following the aspiration the joint was opened through two lateral incisions. The synovial membrane was lightly injected, but not otherwise abnormal. The pus thin, grayish, slightly blood stained, with few white flakes of fibrin. Beneath the patella there was a white mass not adherent, about $1\frac{1}{4}$ in. long and $\frac{1}{2}$ in. wide, which was removed. The joint was then drained with a cigaret drain from side to side.

Following this operation the child stayed in the hospital nineteen days. The wicks were removed from the wound on the ninth day, although a slight amount of discharge persisted. The father took the child home from the hospital against advice on the nineteenth day after operation, with the leg in a plaster cast.

CASE 3. Girl, age 6 months, July 12, 1909. Child gave a history of pneumonia five weeks previously, with discharging ears following three weeks later. Two weeks ago the mother noticed that the left leg was swollen from the hip to the foot. Some mottling of the skin, which passed away in a few days. Hip on left very sensitive. Temperature has been normal except that it would occasionally go to 101 in the afternoon.

The physical examination showed a well developed and nourished infant, with a large swelling over the left hip joint, and extending into groin, which fluctuated. No redness, but very tender. All motions at hip restricted and painful. The temperature was 101.8, pulse 155, respiration 55. The next day the child was operated on. An incision 2 inches long was made just anterior to the trochanter, and the abscess opened. About three ounces of greenish yellow pus evacuated. The capsule was found perforated, and in the capsule a loose piece of cartilage was found, which seemed to be the head of the femur. This was removed. A counter incision was made behind the trochanter and the cavity washed out with salt solution. Rubber tube drain. Culture pneumococcus. The child made an uneventful convalescence, and went home two weeks after the operation with some discharge still persisting from the wounds.

A month later the child was again admitted to the hospital for an abscess in the region of the right hip joint, which seemed to be superficial. This was opened and evacuated, and the child was discharged home four days later.

CASE 4. C. E. L. Age 67, male. Was seen in consultation with Dr. L. B. Clark of Waverley, Mass. Patient had had pneumonia for the past two weeks. The day before the onset of the pneumonia he fell on his right shoulder. The past nine days the shoulder has been swollen and tender, and has been getting worse. The temperature has been irregular, and the past two days the hand and arm have become swollen and edematous.

Examination showed the shoulder joint tense and fluctuating, with the swelling extending down on

the back to the tip of the scapula, where there was a slightly reddened area. A trocar was introduced at this point and pus obtained. Following this the opening was enlarged, and a counter opening was made in front of the joint. Eight to ten ounces of pus were evacuated, and a large drainage tube was inserted.

Following this opening there persisted very profuse discharge, necessitating dressings twice a day for a period of about six weeks, at the end of which time the patient died. After death an examination of the shoulder joint showed extreme disintegration of the cartilage. During life there was great pain on attempted motion, and grating or crepitus could easily be felt. No bacteriological study was made in this case, but it seemed certain that the infection could not be anything other than the pneumococcus. The x-rays of the joint were not very suggestive of destructive processes, and comparison with the well shoulder showed no very marked differences, in spite of the loss of cartilage and bare bone found post mortem.

CASE 5. G. P., girl, age 2 years, 8 months, 12 days. A pale, poorly developed and nourished child. She had been in the Children's Hospital four times before, and had been for long periods in the Convalescent Home of the Children's Hospital at Wellesley. She was an illegitimate child, bottle fed from the start, and had never been strong.

She was first admitted in March, 1913, at the age of one year. The diagnosis at that time was broncho-pneumonia, splenic anemia and splenic tumor. She was in the wards for a month. Her second appearance was in May a month later, and she remained six weeks, the diagnosis being broncho-pneumonia, anemia, otitis media, and a question of syphilis. Her next appearance was in August, 1914, after she had been on the Boston Floating Hospital, where she was taken for a splenic tumor. She had another attack of broncho-pneumonia, from which she recovered, and was discharged in about a month. Her splenic tumor was meanwhile enlarging, and an operation on it was advised, but on account of the child's poor general condition it was postponed after consultation. On Nov. 20, 1914, after having been in the country at the Convalescent Home, she was readmitted to the medical service on account of poor general condition and splenic anemia. On the 25th of November she had the left ear drum punctured for an otitis media. On the 30th the left knee joint became swollen, hot, painful to pressure and motion. Slight edema of left leg. Condition came on in last 18 hours. The day before it had been noted that when the left leg was manipulated the child cried, but no objective symptoms were present. The left ear has continued to discharge. On the first of December, the next day, she was seen in consultation by the orthopedic staff, and it was noted that there were limited motion, flexion, and slight widening of the condyles. The patella did not float. The temperature had been running between 104 and 105 for about a week. An x-ray was taken of the knee joint, which showed apparent periosteal stripping of the lower end of the femur. She was then transferred to the orthopedic service for operation.

On Dec. 4, 1914, the knee was incised in the region of the internal condyle. About one ounce of creamy pus was evacuated from the joint. The finger in the joint passed posteriorly through a large opening in the posterior portion of the capsule.

Four days later she died from apparently general sepsis.

An x-ray taken of the resected knee joint, post mortem, showed suggestions of the same periosteal thickening along the shaft of the femur as seen in life, but section failed to confirm this, and the condition was probably due to edema of the tissues.

The autopsy the next day showed that the base of the brain was filled with rather thick purulent exudate, which extended along over the cortex. The left middle ear contained a small amount of pus. No communication between the ear and meningeal exudate could be established. The knee joint showed edema of the ligaments and polymorphic infiltration. There were a few areas of necrosis in the attached striated muscles.

Bacteriology. Smears from the heart blood and the knee joint showed the pneumococcus, which failed to grow on culture. Injections of emulsified lung were made into mice to obtain a pure culture, but were not successful.

Diagnosis. Diffuse broncho-pneumonia. Spleen: Fibrous splenomegalia (Banti's disease). Brain: Acute purulent meningitis. Knee: Acute purulent synovitis.

CASE 6. Girl, age 1 year, 9 months, 12 days, Nov. 26, 1914. Child had bronchitis followed by pneumonia seven weeks ago. Still has some cough. Has been losing weight. About five weeks ago, immediately following pneumonia, the right knee and lower thigh have been swollen and tender to touch, so much so that she has not attempted to stand or walk. There has been no redness.

Physical Examination. Fairly well developed and nourished child. Lungs show marked dullness at right apex front and back. Over this area are heard bronchial breathing and moist râles.

Local. Patient cannot stand or walk. The right knee and lower thigh are perceptibly swollen, and she tends to hold the knee in about 60° of permanent flexion. The capsule is under tension, and there is definite fluctuation in the joint. The swelling begins just at the tuberosity of the tibia, and in a fusiform manner spreads about the joint and extends up the lower third of the thigh. There is no redness or heat and no definite pain or tenderness. The patella floats. There is $\frac{7}{8}$ in. increase in circumference of the knee. The temperature was 99. Leucocytosis 23,000. Polymorphs 48%. Lymphocytes 52%.

Two days later the joint was aspirated and a serous discharge was obtained, which on culture was negative. The leg was placed in a plaster cast to fix the knee joint. Five days later the temperature rose to 105 and the next day to 105.4. The joint was then opened under novocain by an incision on the outer side of the joint, allowing the escape of a considerable quantity of cloudy fluid, at first, followed by a moderate amount of yellowish pus. A large piece of fibrin flake of a grayish color was also squeezed out, apparently from under the patella. The joint was not explored further, but was irrigated with hot salt solutions and drained by a rubber tube, which passed into the upper portion of the joint. The temperature immediately fell by crisis. The leg was placed in a plaster trough, which was kept on for thirty days. The wound required daily dressings, but there was never any great amount of discharge. The child's general condition steadily improved, and she was discharged home on the thirty-fourth day with the wound

healed, slight thickening about the joint capsule and good motion in the knee joint, which promised to become normal. The pus from the knee joint at the time of the operation showed pure pneumococci. A later culture was taken in an attempt to differentiate the strain or type of the pneumococcus, but the culture proved to be so contaminated that the attempt was abandoned.

X-rays taken of the two knees for comparison before operation and several weeks after, were to all appearances alike. About the joint there was a cloudy appearance as of a swollen capsule, and some indistinctness of bone, but no evidences of bone or cartilaginous involvement, either early or late. The epiphyses were normal.

The extraction of the fibrin flake was of interest, and apparently is a usual condition to be expected in joints infected with the pneumococci. The cocci apparently find lodgment in such flakes, and they should always be expressed by squeezing or by careful extraction if possible so as not to break them up any more than possible.

To sum up, these six cases represent various methods of infection by the pneumococcus, namely:—

1. From the mouth by way of a tooth infection.
2. By trauma without previous known pneumonia.
3. By a previous pneumonia followed by an otitis media.
4. By trauma followed by pneumonia and involvement of the joint in nine days.
5. Following several attacks of bronchopneumonia and immediately after an acute attack of otitis media.
6. Involvement of joint two weeks after an acute attack of lobar pneumonia. This case represents the only typical one.

All these cases had the diagnosis confirmed bacteriologically except Case 4, which, however, I included in this series on account of the improbability of its being anything else. The fluid in all these cases was rather thin and greenish yellow when the joint was first opened, but as it continued to drain at the time of the operation the heavier pus escaped. It was during this period that the fibrin flakes were expressed. The mortality was three out of six cases, 50%. The joints, so far as I have been able to determine, are practically normal in the two cases I have been able to follow.

Clinical Department.

A PRELIMINARY REPORT OF THE RESULT OF WASSERMANN TESTS AS REPORTED FROM DIFFERENT LABORATORIES, CALLING ATTENTION TO A LITTLE NOB ON THE FRENUM OF THE UPPER LIP, WHICH MAY OR MAY NOT BE CHARACTERISTIC OF SYPHILIS.

By O. D. PHELPS, M.D., WORCESTER, MASS.

For the past year the writer has had Wassermann tests done both for diagnosis and as check up for treatment by several different laboratories. Almost every salvarsan administered is accompanied by a Wassermann test; this is the routine on every patient. Each laboratory receives a specimen of the serum for examination, taken at the same time and kept under the same conditions and each laboratory examines the specimen on the same day.

Most specimens here submitted have been to three laboratories, many to four, many to two and a few to five. The result of 358 specimens tabulated for this consideration is as follows:—

FOUR LABORATORIES.

Of 113 bloods—68 agree; 45 disagree.
60.2% agree.
39.8% disagree.

THREE LABORATORIES.

Of 135 bloods—70 agree; 65 disagree.
51.9% agree.
48.1% disagree.

TWO LABORATORIES.

Of 110 bloods—72 agree; 38 disagree.
65.5% agree.
34.5% disagree.

In view of the above table, one might well ask the reliability of the test. The varying results reported in literature of blood from different laboratories and a chance difference in the report of a Wassermann in the experience of the writer are what stimulated this comparison. The table simply shows the delicacy of the test and how susceptible it is to variation in technic, and to differences in the blood as taken at different times.

Craig, working for the most part in the Government Laboratories of the U. S. Army at Fort Leavenworth, Kansas, finds that the only other diseases aside from syphilis which may cause a Wassermann to be positive are yaws, leprosy, relapsing fever, and febrile stage of certain malarial infections.

It is a fact that a positive Wassermann test done in a reliable laboratory and confirmed by a second examination is diagnostic of syphilis. As to a negative Wassermann very little reliance

can be placed on a single test. In early primary syphilis when the diagnosis is most needed, the reaction is often negative. The secondary stage is the one in which the Wassermann is most often positive.

The writer has observed the phenomenon of a Wassermann being reported negative in a case and the same to be reported strongly positive shortly after with no apparent reason.

Alcohol seems to have a distinct effect on the Wassermann reaction, in rendering it negative. A patient of the writer was seen in 1911 with an unmistakable macular rash, extending over face, chest, abdomen and extremities. The patient was accustomed to use beer constantly and each Wassermann report was negative. During all of his treatments, which have been more or less consistent up to last summer, but one out of several Wassermann tests has ever been positive. He yielded very nicely to salvarsan and mercurial treatments, but during his whole course we have been unable to depend on the Wassermann test to check up his progress.

For some time the writer has been observing a little tab, a nob on the frenum of the upper lip of patients. So far as known, nothing has been written of it, and it is probable that the nob is found as frequently among non-syphilitics as syphilitics.

The following observations have been made from 359 cases.

	Present.	Absent.	Present.	Absent.
			%	%
S-1	17	6	73.9	26.1
S-2	37	28	56.9	43.1
S-3	94	51	64.8	35.2
Total S's	148	85	63.5	36.5
U	48	21	69.5	30.5
Total G-U	196	106	65.0	35.0
Misc.	41	16	72.0	28.0
Total obser....	237	122	66.0	34.0

NOTE. S-1, S-2, S-3, denotes Primary, Secondary and Tertiary Syphilis. U refers to Urethritis.

Pathologically the nob is reported connective tissue covered by epithelium.

THE FEMUR OF AN IDIOPATHIC EPILEPTIC.

By J. S. FOOTE, M.D., OMAHA, NEBRASKA.

Professor of Pathology, Creighton Medical College, Omaha, Nebraska.

As the pathology of idiopathic epilepsy is obscure, the following case is interesting and suggestive:—

Male, age 40, giving a history of epilepsy from childhood, had been under observation for some years in one of our state institutions. On the day of his death he had twenty convulsions.

A three-inch middle piece of the femur was obtained for microscopical examination. After boiling the bone until the medullary contents were removed, a section through the middle of the piece was ground

to proper thinness and mounted. A drawing of the section was then made with the Edinger apparatus and appears below.

Section through the middle of the femur of an idiopathic Epileptic - age 40.

The wall of the bone varied in thickness from 1 mm. to 2 mm. The medullary surface was finely reticular, and the canal was filled with friable matter. The medullary index or ratio of the medullary canal to the bone was 27.7%. The average index of 139 other human femora was found to be 38%. The bone was extremely light and, in places, translucent.

Structure: The external circumferential lamellae were fragmentary. The narrow central ring was composed of small, irregularly shaped Haversian systems, some of which were senile.

The internal circumferential lamellae formed a narrow fragmentary ring around the medullary canal, indicating that the wall of the bone had never been any thicker.

The case is presented merely to call attention to the osseous system in idiopathic epilepsy.

"The Significance of Acroataxia and Proximal Ataxia of the Extremities in Differentiating Between Disease of the Peripheral Nerves and Spinal Cord Disease." By C. F. HOOVER, Cleveland, Ohio.

In a former communication it was shown that in ataxic states of the extremities two varieties may be differentiated: one in which the distal muscles are involved, called acroataxia; another in which the proximal muscles are involved, called proximal ataxia. In a case of primary anaemia, stereognosis was preserved and no ataxia in the ordinary sense was observed; but extreme ataxia of the intrinsic muscles of the hands and feet was found. In 52

further cases of primary anaemia at the Lakeside Hospital acroataxia has been noted, with proximal ataxia added as a late manifestation. In lead and alcoholic ataxia, however, the relation of the time of appearance of the two forms is reversed.

In spinal cord disease, proximal ataxia appears much sooner than acroataxia: in the ataxia of the anaemic type, on the other hand, no Romberg sign may be elicited because the ilio-femoral muscles are not involved.

In a case of diabetes with apparent diabetic neuritis, the presence of proximal ataxia without acroataxia was noted; examination of the spinal fluid revealed tabes as the cause and the ataxia improved under antisyphilitic treatment.

The writer has been able to diagnose primary anaemia in patients over 50 by the presence of acroataxia and loss of vibratory sense independent of blood examination. In a man with an obstructive prostate there was a proximal ataxia without acroataxia. The spinal fluid being normal, the diagnosis of cancer of the prostate with metastasis in the cord was made and confirmed.

In a case of apparent primary anaemia, with a mass in the left hypochondrium, there was loss of reflexes and proximal ataxia without acroataxia; the diagnosis of hypernephroma with metastasis in the cord was made and confirmed.

"The Present Status of Hygiene or Public Health and its Future in America." By W. W. FORD, Baltimore, Md.

The growing demand for public health officers and for public instruction in hygiene makes it necessary to formulate the underlying principles which should be considered in meeting this demand.

Pettenkofer founded the science of public hygiene and in Germany and Austria his teachings received ready practical application, spreading thence largely all over Europe. As a result of his campaign the mortality from zymotic diseases fell. The great fruits of this work ripened in the decade 1870-1880, but with the advent of bacteriology Pettenkofer's work had a set back. Bacteriology became hygiene for a time, until lately when Pettenkofer's plan has been revived, modified by bacteriology.

In Great Britain, since the sanitary laws of 1848, public health matters have been on a sound basis, but the emphasis has been on public works, such as water supplies, drainage, sewage disposal, etc. Preventive medicine is the gift of France, but it has been twisted by the work of the Pasteur Institute. Thus it may be seen that the science of public health has been prominent and in the public consciousness of European countries for many years, and the subject is a major matter in the universities of Germany, Austria-Hungary, Great Britain and France. But it is still neglected in this country and chaotic ideas on the subject prevail. The Departments of Health in states and cities have long recognized the needs of the situation, but the national government still lags behind, notwithstanding the work done by the Public Health Service.

In the medical schools, teaching of hygiene was begun at the Woman's Medical College of Philadelphia in Pettenkofer's time. The subject has gradually appeared in the curricula of all medical schools but at this time it is a major subject in only five universities; a pitiable condition as compared with the situation abroad.

43

"The Alleged Relation Between Vaccine Virus and Post-Vaccination Tetanus." By JOHN F. ANDERSON, Washington, D. C.

Since 1902 the public health service has supervised the manufacture of and commerce in biological products. Among other things, it has conducted an investigation of the occurrence of tetanus following vaccination. Since 1904 the writer has studied this subject and the paper gives a summary of results.

There were four lines of study:

1. Study of actual cases, by personal investigation or by a delegated officer, with collection of data upon incubation period, kind and source of virus used, collateral circumstances, etc.
2. The incidence of tetanus among large groups vaccinated at the same time: army, navy, etc.
3. Examination of commercial vaccines for the presence of tetanus bacilli or spores.
4. Laboratory observations on animals vaccinated with virus infected with tetanus.

1. Forty-one cases of post-vaccination tetanus were studied. In no cases were tetanus spores found in virus from same stock as that used for the vaccinations. The incubation time was 9 to 20 days: mortality about 75%. The mortality was less in cases with incubation time of 10 days.

2. Among 385,000 persons vaccinated in U. S. Army there were 6 cases of tetanus, none of which had any relation to the vaccination.

Among 200,000 persons vaccinated in U. S. Navy there were two cases of tetanus having no relation to vaccination.

3. Examination was made of enough virus to vaccinate 200,000. In no single instance was tetanus found.

4. Animals were vaccinated with virus containing large numbers of tetanus spores. Rhesus monkeys and guinea pigs, animals susceptible to both vaccine and tetanus, all escaped tetanus although the vaccination crusts sometimes contained spores. This fact leads to the belief that there is no danger even if virus does contain spores.

The conclusions reached:

1. Vaccine virus on the market does not contain tetanus spores.
2. Tetanus following vaccination depends upon accidental infection at the time of crust formation.

44

"Recent Application of Chemotherapy with Special Reference to the Action of Emetin Upon Endameba Buccalis, the Specific Cause of Alveolodental Pyorrhea." By C. C. BASS, New Orleans, La.

It has been shown that the endameba buccalis is present in the lesions of all cases of Riggs' disease. This endameba can not be cultivated in vitro; it is necessary, therefore, to judge the effect of drugs upon the organism by observations on living individuals. The destructive effect of emetin on cultured amebae was demonstrated by Rogers, and he thought that the same effect could be demonstrated on pathogenic amebae.

The writer has evidence that emetin does poison endameba buccalis. The drug will kill living tissue cells if they are exposed long enough to a strong solution. If introduced into the blood stream of animals in sufficient dosage death follows. The minimum lethal dose in man is thought to be 6

grains intravenously. In determining dosage it is necessary to come well within safe bounds: one tenth the minimum lethal dose should be regarded as reasonably safe. Such a dose is sufficient to kill endamebae when exposed to that concentration in the serum. When emetin is used in half grain doses in Riggs' disease, endamebae disappear with varying rapidity; a few disappear after the first injection; a larger number after a second, and with increasing rapidity after repeated doses. Some cases are very resistant. Positively cured cases are hard to demonstrate but they may be free of amebae for months. Reinfection takes place in some cases.

The food of *endameba buccalis* seems to be a certain cell to be found at the bottom of pus pockets; the lesions are probably produced by the efforts of the amebae to reach these cells and by the destruction of the cells. Emetin may produce its effect by interfering with the food supply of the amebae.

45

"Studies on Uric Acid Metabolism in Gout." By JOSEPH H. PRATT, Boston, Mass.

Folin first described a trustworthy method of estimating the uric acid in the blood. In 1913 the writer reported uric acid estimations in 9 cases of gout; since then he has had 7 additional cases under personal observation and has studied the blood. The disease is a rare one in this country; his cases had been few and no general conclusions could be offered. Some facts are offered, however.

On purin free diet, the average uric acid content of the blood of gouty patients was 3.7 mg. per 100 gm. blood. In normal individuals, on mixed diet the uric acid average is 1.8 mg. per 100 gm. blood; 2.5 mg. is the upper level in normal persons.

One cannot make the diagnosis of gout from a single examination of blood, because the uric acid in the blood may be normal at times in gout.

A single high uric acid finding is not sufficient for the diagnosis of gout, because it may be high in other diseases, even as high as 5.0 mg. per 100 gm. blood.

The blood of patients on rich purin diet has been studied; the sweetbread meal was used. One patient whose blood uric acid was 1.6 mg. (lowest in the literature) on the fourth day reached 4.0 mg. per 100 gm. blood.

There was a variable behavior in different cases: after the sweetbread meal there may be a drop in uric acid for a day or two, with later a sharp rise. In healthy persons there is a distinct rise in four hours after the meal.

It could not be suggested that the method will have any diagnostic value.

46

"Open Air Treatment of Pneumonia and Anemia in Children." By ROWLAND C. FREEMAN, New York, N. Y.

The paper gives the results of fresh air treatment of small children in Roosevelt Hospital. The best results, compared with controls in the ward, were in cold weather. No increase of blood pressure was noted as a result of out door treatment; the most marked results were increased color in cheeks, diminished cough, better sleep. There was reduced spread of contagion; there have been cases of measles on the roof without spread.

Greatest interest centred in three cases of blood abnormalities treated in this way. 1. A child with

simple anaemia (25% hemoglobin), bronchitis, and colitis. Red cell count of 280,000 went to above 1,000,000 in a surprisingly short time. This child had also Syr. Fer. Iodid, but the improvement was out of all proportion to the drug given.

2. A child with leukaemia had rapid improvement of lungs, spleen, and blood.

3. A child with splenic anaemia, showing normoblasts, megaloblasts, 60,000 white cells, etc. Improved rapidly on the roof; relapsed when returned to the ward, and improved again when put out of doors.

Summary of 120 cases of pneumonia treated in open air: 21 cases of uncomplicated lobar pneumonia had normal temperature in 3 days after admission. Mortality of lobar pneumonia cases 4.1% 31 cases of broncho-pneumonia were normal 7 days after admission. Mortality in this form was 3.4%.

47

"A Brief Note on the Value of Pituitary Preparations (Posterior Lobe) in Acute Lobar Pneumonia." By S. SOLIS COHEN, Philadelphia, Pa.

Ordinarily we expect children under 12 to get well of acute lobar pneumonia, with only good nursing and, of course, open air. But occasionally treatment is required as in the case of a child just over 12, who came into the hospital with pneumonia; there was delayed resolution during which there was a tendency to collapse and it was necessary to use oxygen; this child was much helped by extract of the posterior lobe of the pituitary gland and survived a complicating pneumothorax.

When we find a specific biologic cure for pneumonia we shall be fortunate, but we shall still need to use tactical measures in connection with the general strategy. Pituitary extract will then be a valuable tactical aid. Pituitary substance raises the blood pressure. When we find the systolic pressure below the pulse rate there is danger. And when we find the diastolic pressure approaching the respiratory rate there is danger. In both cases pituitary extract will do good. It will also diminish dangerous tympanites.

Until we find an available specific, we must continue to employ skillfully fresh air, nursing, quinin, pituitrin. Even now, we have more cases of delayed resolution because more live to have it. This is best treated by the use of autogenous vaccines given by mouth.

"Pathognomonic Changes of the Cerebrospinal Fluid in Nervous Diseases." By JOSEPH COLLINS, New York, N. Y.

Although we do not know the origin of the spinal fluid, we do know something about its alterations in disease.

The fluid has been studied at the New York Neurological Institute in about 20,000 cases. Such examinations are useful in the study of cerebrospinal lesions due to the tubercle bacillus, to the diplococcus meningitidis, to the organism of epidemic poliomyelitis, and to the spirochaeta pallida.

We are now able to distinguish between meningeo-vascular and the parenchymatous syphilitic lesions of the central nervous system, tabs being the type of the one and paresis of the other.

In 167 cases of tabs, there were 121 positive findings; the remaining cases had had very thorough antisyphilitic treatment. In 140 cases, there were pathognomonic signs in the fluid.

There are three types of tabs from the serological point of view: 1. Typical, classical type; 2. Hyperlymphocytic type, in which the meninges are also involved; 3. A type in which the Wassermann reaction is weak, the globulin contents low, cells number only about 20, and Fehling's solution is not always reduced.

In 85 cases of paresis, 53 were serologically typical: + Wassermann, modified pleocytosis, + + globulin, + Fehling's solution. A pathognomonic test is the reduction of colloidal gold; this test was positive in every case except one. This reaction was found to occur also in two instances in 27 cases of disseminated insular sclerosis, but in these paresis could not absolutely be ruled out.

Treatment affects the serological findings in both types of central nervous syphilis; many reports and histories of cases from hospitals in this country give no statement as to the effect of treatment on the fluid.

54

"Further Observations on Pain in Diaphragmatic Pleurisy." By JOSEPH A. CAPPS, Chicago, Ill.

Pain as symptomatic of pleural lesions had been studied by mechanically irritating the membrane in thoracentesis operations. The visceral layer is not responsive to pain; the parietal pleura is very responsive to irritation and sense of location is precise; the diaphragmatic pleura is sensitive but the pain is referred from the marginal area to the abdomen, from the central area to the neck. This experimental work has been supplemented by clinical observations on diaphragmatic pleurisy; 22 cases of simple pleurisy, 29 of pleuro-pneumonia. There was referred abdominal pain in 54 cases, of the same character as that produced experimentally. A phenomenon not noticed in experiments was that in 50% of the cases the point of maximum pain corresponded with the point of maximum tenderness to pressure. The most common points of referred pain in the abdomen are above and to the right or left of the navel.

There was referred neck pain in 31 cases. This had the same characteristics as the abdominal pain; the painful spots appear mostly along the ridge of the trapezius. In the neck the points of maximum pain and tenderness always coincide.

Nine of the cases were at first diagnosed appendicitis; two were operated with negative findings. Six were called cholecystitis, two operated with negative findings; two were called ulcer of stomach, one operated; two, abscess of liver, one operated; one, renal calculus; one, lumbago; one, abdominal inflammation of uncertain character.

Differential diagnostic criteria are given. Subphrenic inflammations give rise to direct pain as well as to referred abdominal pain; the neck pain

gives no evidence as between sub- and supraphrenic inflammation.

Thursday morning, May 13.

55

"The Presentation of a Case of Herter's Infantilisim." By M. HOWARD FUSSELL and W. B. BRAMLETT, Philadelphia, Pa.

In 1908 C. Herter reported five cases characterized by chronic gastro-intestinal intoxication, with retarded skeletal growth; there were present intestinal disturbances, a mild anemia, and atrophy of all the tissues of the body. The disease was believed to be due to a persistence of the infantile type of intestinal flora. It is not known whether the intestinal bacteria are responsible for the fact that calcium is not absorbed but is lost through the intestinal canal in the form of soap. The only effective treatment is dietetic; proteids are borne best; carbohydrates, worst. It was found that gelatin is the best form of proteid, as it does not give rise to putrefactive products.

Fussell's case was given the following dietary: Breakfast, milk, gelatin, and one soda cracker; lunch, 6 oz. milk, gelatin and two soda crackers; dinner, straight beef, beef juice, and green vegetables. The child was nine and a half years old; 54 inches high; weight, 24 pounds. It had been treated for all sorts of conditions and was admitted to the hospital as a case of nephritis. Albuminuria cleared up with rest and diet. Wassermann negative in blood and spinal fluid. Radiographs of the wrists showed a development age of 2½-3 years, according to the Rotech standard; this corresponded to weight, height and eruption of teeth. The temperature was elevated until put on the diet. There has been no change in the wrist bones, but the child is heavier, fatter, and stronger; it laughs, talks, and runs about; it has gained an inch and a half in height and 12 pounds in weight.

56

"Clinical Studies of Several Types of Acute Leukaemic States." By L. F. BARKER and W. A. BAETJER, Baltimore, Md.

The studies cover 21 cases* of acute leukaemia recently under treatment. The disease is recognized to be not only a change in the total cell count but also a specific change in the blood-making organs. Acute and chronic forms are seen: the acute cases die early as a rule; those of the chronic variety live longer. The chronic cases may begin with acute manifestations, or the disease after a long chronic course may have an abrupt acute termination.

The acute cases are more often recognized now because the blood is oftener studied. They are sometimes mistaken for acute sepsis, but in any such cases associated with stomatitis and hemorrhagic diathesis, acute leukaemia should be suspected. It is necessary for diagnosis to consider both the clinical course and the blood. The exact type may require post mortem histological study for classification. There may be at the beginning and end not a leukaemia but a leukopenia. Cases, with blood pictures, are given in detail.

57

"Colloid Carcinoma of the Peritoneum." By THOMAS MCCRAE and W. M. L. COPLAN, Philadelphia, Pa.

The case was presented on account of the unique pathological and clinical pictures it furnishes. The patient was a man who for 4 years suffered from ascites; there were no diagnostic evidences available until the end of the 3rd year when fluid withdrawn by tapping was found to contain colloid material resembling tapioca grains. In the last month of life freely movable tumors could be felt in the abdomen. A terminal symptom was obstinate diarrhea; food taken could be recognized in the stools 3 or 4 hours later. The salient features were: the presence of a marked ascites for 4 years with preservation of excellent health; the finding of colloid material in the ascitic fluid; the development of movable tumors. (Presented by Dr. McCrae)

Dr. Coplin exhibited photomicrographs of the tumors. The interesting feature was the retrogression of the epithelial inclusions with the production of colloid.

"Spontaneous (Non-Tubercular) Pneumothorax." BY ELSWORTH SMITH, St. Louis, Mo.

59

"Observations by Krogh's Method of Blood Flow in Human Subjects." BY J. H. MEANS and L. H. NEWBURGH, Boston, Mass.

The observations were undertaken to determine the effect of caffeine on blood flow. The method of Krogh and Libhard was used. Figures and tables are given setting forth the details of the work.

The average coefficient of utilization of oxygen is 41%. In trained athletes the coefficient is higher than normal, showing that the circulation is very economical. In a case with double aortic and mitral disease the coefficient was found to be normal. Normal subjects at rest when treated with caffeine sodio-salicylate were found to have a great increase of blood flow without increase of oxygen absorption. Under measured work, the increase of blood flow and oxygen utilization is parallel. Caffeine caused no marked change in this. In work, the increased demand for blood is met first by increased ventricular output up to a certain point when increased pulse rate takes up the additional burden.

60

"Alcukaemic Lymphadenosis." BY T. B. FUTCHER, Baltimore, Md.

The patient was a single woman, aged 58. Her symptoms were dyspnoea and weakness with enlargement of axillary, cervical, inguinal and post-peritoneal glands. The blood count found 7,000 leukocytes, 67% of which were large and small lymphocytes. The heart and kidneys were normal. Diagnosis rested between Hodgkins' disease and an atypical leukaemia. The leukocytes during her stay in the hospital ranged between 7,000 and 14,000 in number; large and small lymphocytes constituted from 67% to 90%. Wassermann and tuberculin reactions were negative. A gland was removed: cultures were negative; histologically, it showed a chronic lymphadenosis, resembling lymphosarcoma. Hodgkins' disease was not simulated. Treatment with cacodylate of soda resulted in clinical improvement but did not improve the blood. There is now a metastatic nodule in the eyelid. The case must be regarded as one of Nageli's alcukaemic lymphadenosis, in which there is no change in the total white cell count, but a great change in

the differential picture. The disease is very chronic and is characterized by a tendency to the development of metastases in the skin. The course may abruptly become acute with an early fatal termination.

61

"The Condition of Patients after Partial or Complete Resection of the Colon." BY J. C. BLOODGOOD, (by invitation), Baltimore, Md.

Comparison is made between two groups of cases in which resection of a small portion of the ileum and the right colon to the transverse portion has been done. 1. Those cases in which the operation was done for local disease, ulcer or cancer; 2. Those in which the resection was done for a more general condition, *i. e.*, thinning of walls, dilatation, atony.

As to immediate results: in resection for local disease the patients are apt to have diarrhea for a few months; in resection for the general condition, the remaining colon being abnormal, there is no diarrhea. In local disease cases, bladder irritation accompanies the diarrhea and disappears with it. Bladder irritation does not occur after resection in the atonic cases. Cases in which the operation was done for local disease have never come for secondary operation. When resection was undertaken for the atonic disease, the same technic which had been satisfactory formerly was chosen in the first cases.

Out of 28 personal cases of the atonic type, 16 are well: that is to say they have gained weight, required no cathartics, have no indigestion, no adhesion pains, etc. The convalescence is slow, (it is rapid after ulcer and cancer cases) and may require 2 years. The majority of the cases are women, and are able to do their own house work.

After four years' observation of resection in cases of atonic disease and seven years observation of local disease cases, it is evident that removing the right colon does no harm.

What of the failures in the atonic cases? Seven were failures in that they had post operative discomfort and pain. Reoperated cases indicate that the failures were due to the use of side to side anastomosis; the two blind extremities become tense and painful diverticula; this does not happen in ulcer and cancer cases. In the last three cases end to side anastomosis has been employed.

The paper does not discuss the justifiability of the operation, but undertakes to show that no harm results from resecting the right colon; and that the technic of the operation in atonic cases must be especially careful.

That resection has an effect on the atony is shown by a case in which there was vomiting, with food retention in stomach and stasis in colon; 18 months after the operation there was no vomiting and there was hypermotility of stomach and colon. All of the atonic cases had been referred by medical colleagues: all had been treated thoroughly; all other means of relief had been tried and had failed. All of the 16 successful cases are much improved; but they are not robust. Their atony is a terminal condition which might have been prevented by proper medical treatment.

62

"The Fate of Fats in the Blood Stream." BY WM. CHARLES WHITE, Pittsburgh, Pa.

Light fats were injected into the blood stream

in an effort to learn why tubercle bacilli lodge preferably in the upper lobes of the lungs. Cream was injected into the ear vein of rabbits. It is rapidly set aside into the lymphatics and concentrated in the cisterna chyli. There was no evidence that any of the fat was conveyed into any of the organs by the blood vessels. All of the fat is held up in the pulmonary circulation and it does not get out again into the peripheral circulation. It is found later not only in the depots of fat but also outside the central veins in the lobules of the liver. Suggestion is made of a lymphatic circulation in the liver connected with the cisterna chyli.

63

"An Unusual Type of Pulmonary Mycosis." By THOMAS R. BOGGS and M. C. PINCOFFS, Baltimore, Md.

The case was one of a mycotic lung infection not heretofore reported in the United States. A native American girl, a corn scraper in a canning factory, sought relief for a boil-like lesion under the arm. She was found to have cancer of the breast on the same side; there was weakness, numbness and tingling of the arm, evidences of circulatory obstruction in the axilla. Operation for breast cancer and axillary condition was done; no evidence of pulmonary disease was noticed. Later she entered the City Hospital febrile, prostrated and with profuse expectoration of sputum resembling that from liver abscess. In the sputum were found mycelium and spores. The course was rapidly downward; on the fifth day hemoptysis occurred, cough ceased and later hemorrhage from axillary sinus marked the end. Autopsy revealed cavity communicating with pleura and sinus; the lung was in organized grey hepatization.

The organism grew abundantly on culturing and was found to be a moniliform yeast. It is pathogenic to animals when inoculated and when given intratracheally; not when given by mouth. It is easily overlooked in the sputum by ordinary staining methods; it is necessary to culture by the plate method to recover the organism.

64

"Studies in Moniliasis of the Digestive Tract in Porto Rico." By BAILEY K. ASHFORD, San Juan, P. R.

(Similar paper, *Journal A. M. A.*, June 5, 1915).

Clinical and pathological examinations have shown a close connection between sprue and the use of diseased yeast and undercooked bread. A monilia, differing from monilia albicans, has been grown from the tongue of patients suffering from sprue in 100% of the cases examined. It has been grown from the tongue of patients with suggestive histories of sprue in the past in 21% of the cases. In 31 cases free of symptoms or history of sprue, only one yielded the monilia from tongue culture. The organism has been found in cases of so-called thrush, in many cases of ill-defined illness characterized by fermentative dyspepsia, and in 100% of cases of true sprue; these facts lead to the suggestion that there exist tongue sprue, intestinal sprue, and a combination, complete or true sprue.

The monilia in question has been found in the centre of loaves of bread; the baker's yeast in Porto Rico is subject to variations from type; sprue is a

disease of urban communities where bread is eaten, being extremely rare in rural districts where bread is not a part of the dietary. Dr. Gonzales Martinez has devised a complement fixation test which has been found specific in many cases of sprue, Sprue is controlled, and in many cases cured, by the use of a non-carbohydrate diet, in which the monilia will not grow.

Book Reviews.

Encyclopedin Medica. Second edition, under the general editorship of J. W. BALLANTYNE, M.D., C.M., F.R.C.P.E. Vol. I. Edinburgh and London: W. Green and Son, Ltd. 1915.

This volume opens the publication of the second edition of one of the leading standard medical encyclopedias. The general plan of the work and the mode of arrangement of the articles which characterized the first issue have been retained as far as possible. In the first volume, which includes the subjects from abattoirs to asphyxia, many new articles have been added on such topics, for example, as acidosis, acromegaly, adenoids, amebiasis, ankylostomiasis, ante-natal pathology and ascites. Many new drugs have also been discussed, including those appearing in the British pharmacopoeia of 1914. In the subject of anatomy there is presented a critical discussion of the Basle anatomic nomenclature, with an elaborate table giving in parallel columns the old terminology, the Basle terminology, and a suggested English equivalent for the latter. This table should be of especial value to teachers and to practitioners who are endeavoring to replace their old terminology by the new, and who prefer English phraseology to the Latin terms of the Basle nomenclature. For the present the old anatomic terms have been retained in the text of the encyclopedia, but it is suggested that in a future edition these may be wholly replaced by the B. N. A. terms. The present article is a valuable aid in establishing the transition during this period of anatomic interregnum.

Naturally many new authors appear in this edition, men for the most part of international eminence in the British profession. Where older work has been retained it has been thoroughly revised. The volume is illustrated with a number of excellent text figures and full page plates, several of the latter being in colors. At the close of many of the articles is presented a bibliography on the subject in question. The first volume presents abundant promise for the continuation of an important and valuable work of medical reference.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, SEPTEMBER 9, 1915.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

The editor will be in the editorial office daily, except Wednesday and Saturday, from one to two-thirty p.m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

EDUCATION AND EUGENICS.

IN the issue of the JOURNAL for August 26, we commented editorially on some of the eugenic, or rather dysgenic, effects of modern methods of warfare. Two writers in recent issues of a contemporary daily publication* have similarly commented on the dysgenic effects of certain modern educational and social movements. Without reviewing the entire scope and bearing of these movements, it may be of interest to discuss briefly, in the light of previous evolutionary experience, the possible result of some of these influences on the future of human civilization, limiting the consideration to those proceeding from the so-called higher, or collegiate, education.

Without discussing exact statistics, it may fairly be acknowledged that, with the notable exception of certain families, collegiate education, among both men and women, appears to lead to a marked decrease in racial fecundity.

Probably this is because the various recognized factors of decreasing fecundity among civilized peoples operate more intensely upon the highly educated than upon others. These influences at present seem to affect college-bred women even more than men, possibly because of their more limited reproductive period and their greater temptations away from marriage.

In an article in the *Journal of the American Statistical Association* for June, 1914, Nellie S. Nearing concludes as follows her investigation of the then available marriage statistics of the women graduates of colleges in America:—

"The decade 1890 to 1899 is undoubtedly the most fairly representative (as respects marriage rates). On the one hand, it falls within the epoch which accepted college education for women and looked upon it as thoroughly respectable. On the other hand, the graduates in the latest graduating class (class of 1899) are now at least 35 years of age. The marriage record of the decade is therefore fairly complete.

"The eight colleges graduating more than 100 students each during the decade (Earlham, Swarthmore, Wilson, Indiana, Vassar, Radcliffe, Wellesley and Bryn Mawr), show fairly uniform marriage rates. The lowest is Bryn Mawr, 41.8 per cent. (294 graduates), and the highest Swarthmore, 58.7 per cent. (148 graduates). It is probable that the marriage rate for this decade is fairly representative of the tendency in the modern women's college world."

Moreover, the average fecundity of married college graduates is low. Let us quote only two examples from the paper of the authors above mentioned:—

"The marriage rate of Yale graduates had declined to 66.3 per cent. for the period 1867-86, a period long enough to furnish a basis, and Prof. William B. Bailey, the statistician, has calculated from the class records that the average number of children born to the married graduates of these classes when all their families are complete is 2.3. (*Yale Review*, November, 1908, p. 337).

"The graduates of 1870-89 at Vassar and of 1880-89 at Wellesley numbered 1277, and had borne by 1912, when the members of the youngest class would average 45 years of age and their families be complete, a total of 1197 children, or 93.7 for each hundred graduates.

"So that every hundred Yale graduates produce 152.5 children and every hundred Vassar and Wellesley graduates produce 93.7 children."

Whatever the causes, the fact seems to remain that, for better or for worse, the members of the more highly educated class in America are barely holding their own genetically, cer-

* *Boston Herald*, Aug. 29, 1915, page 6, and Sept. 6, 1915, page 7.

tainly not showing the normal reproductive increase, probably being steadily eliminated racially and replaced by newer stocks without an ancestry of education.

From this phenomenon the authors draw most gloomy eugenic conclusions. The best stock is constantly perishing and being succeeded by the less worthy. There thus tends to be established "an unnatural selection of the fittest to die and the unfittest to survive."

Doubtless these are indeed considerations to give us pause, yet perhaps the situation is not so serious as it may appear. One crux of the question lies in the definition of fitness. Fitness to survive is not a matter of intellectual, physical or moral qualities alone, but of that combination of the three which happens to be best adapted to meet the conditions of existing environment. Successful racial, class or family fecundity is therefore dependent on qualities belonging to all these groups. Now, as man, like all other forms of life past and present, pursues his evolutionary course, he is constantly encountering new environmental conditions, and in the process of adaption to these conditions, it is inevitable that many, often otherwise highly valuable and efficient stocks, should perish, until that one has been selected to survive which can best meet the new demands. This may seem wasteful, but the infallible natural method seems to be one of ultimate conservation though apparent prodigality.

Education is one of the more recent of these newer environmental conditions which the human race has encountered, and we are now witnessing the process of selective adaptation thereto. The process is perilously destructive, but those who are in the forefront of battle must expect the highest casualties. Doubtless many stocks of high arboreal efficiency perished in the transition to the erect bipedal terrestrigrade habit. Ultimately the transition was successfully made and proved worth while, though its physical evil effects are still observable in tendencies to hernia and ptosis. The same will probably prove true of higher education: it is dangerous, but on the whole its advantages will outweigh its disadvantages, even eugenically. In time, probably, only those will survive who really desire offspring, and the superior conditions and heredity which such persons, as parents, are likely to provide for their descendants, may prove an immense and controlling evolutionary advantage.

Lamentable though it may appear, racial experience indicates that the constant perishing of valuable stocks is not an irretrievable calamity. This is the price of evolution, as "blood is the price of admiralty." Through all past time, natural process has succeeded in steadily advancing the quality of its product from crude material. For though the fine stock may perish as such, its achievement for the race is not necessarily lost. Each generation of mankind, whatever its discrete eugenic or dysgenic antecedence, is still collectively

"Heir of all the ages

In the foremost files of time,"

TUBERCULOSIS CONFERENCES.

It is announced by the National Association for the Study and Prevention of Tuberculosis that a series of five sectional conferences has been arranged to take place during the coming fall. These conferences will be held respectively at Indianapolis, Ind., El Paso, Tex., Columbia, S. C., Springfield, Mass., and Albany, N.Y. The chief subjects for discussion at each will be the various methods of carrying out more effectively both by physician and by the laity the national movement for the control and suppression of tuberculosis.

"The Indianapolis meeting, to be held September 29th, 30th and October 1st, will be known as the Mississippi Valley Tuberculosis Conference and will include the states of Ohio, Indiana, Illinois, Michigan, Wisconsin, Kentucky, Tennessee, Arkansas, Missouri, Iowa, Minnesota, Kansas, Nebraska, South Dakota, North Dakota, Montana, Wyoming and Colorado.

At El Paso the Southwestern Health Conference will meet September 27th to October 1st and will discuss not only tuberculosis, but other health subjects. This conference includes Texas, Oklahoma, New Mexico, Arizona, California, Nevada, Utah and Colorado.

The Southern Tuberculosis Conference at Columbia will meet October 8th and 9th, and will devote considerable attention to the problem of the tuberculous negro. The states included in this group are Alabama, Arkansas, Florida, Georgia, Louisiana, Mississippi, North Carolina, South Carolina, Tennessee, Virginia and West Virginia.

The New England Tuberculosis Conference will embrace the six states of Maine, New Hampshire, Vermont, Massachusetts, Connecticut and Rhode Island. This conference will be held on October 22nd and 23rd.

The North Atlantic Tuberculosis Conference will be held at Albany during the week of November 1st. It will take in the states of New York, Pennsylvania, New Jersey, Maryland, Delaware and the District of Columbia."

The New England Conference, which is the second to be held in this district, is to be under the immediate administration of the Massachusetts Anti-Tuberculosis League, and a cordial invitation is extended to all physicians to attend the sessions and take part in the discussion. The purposes of the conference are to bring together anti-tuberculosis workers, to discuss matters of special interest to the New England States, and to bring the facilities and aid of the National Association for the Study and Prevention of Tuberculosis more closely to bear on the problems involved. The following is a preliminary tentative program of the sessions of the New England Conference. The complete program will be published in a later issue of the JOURNAL.

FIRST SESSION.

Programs of Anti-Tuberculosis Work.

1. For cities of 100,000 or over.
2. For cities of less than 100,000.
3. For small towns and country communities.

SECOND SESSION.

Red Cross Seal Sales Methods.

An informal discussion will take place at a dinner session.

THIRD SESSION.

Industry and Tuberculosis.

1. The medical examination of employees.
2. Employees' relief and aid associations.
3. Insurance against tuberculosis.

FOURTH SESSION.

Methods of Anti-Tuberculosis Work.

1. Educational methods.
2. Nursing.
3. Dispensaries.
4. Institutions.

FIFTH SESSION.

The Diagnosis of Incipient Cases of Pulmonary Tuberculosis.

1. Lecture on "What the general practitioner should know about tuberculosis."
2. Clinical demonstration, showing how to detect early tuberculosis.
(This session may be held simultaneously with one of the other sessions and will be arranged especially for physicians.)

The National Association has arranged for expert speakers to present various subjects and lead in the discussion. The officers of this second New England Tuberculosis Conference are as follows:—

PRESIDENT.

Dr. Stephen J. Maher, New Haven, Connecticut.

VICE PRESIDENTS.

Hon. Redfield Proctor, Proctor, Vermont.

Dr. Estes Nichols, Hebron, Maine.

Dr. Harry Lee Barnes, Wallum Lake, Rhode Island.

Dr. Edward O. Otis, Boston, Massachusetts.

Dr. John M. Wise, Glencliff, New Hampshire.

Dr. David R. Lyman, Wallingford, Connecticut.

SECRETARY.

Seymour H. Stone,

4 Joy Street, Boston, Massachusetts.

It is earnestly to be hoped that there will be a large attendance at this local New England Conference, as well as at all the others of the series, on the part not only of physicians but of all persons interested in public welfare work. Any communications or suggestions should be addressed to the local secretary, Mr. Stone, or to Mr. Philip P. Jacobs, the assistant secretary of the National Association.

PHYSICAL TYPES AND PROFESSIONAL EFFICIENCY.

As the leading article in the issue of the JOURNAL for March 4, 1915, (Vol. CLXXII, page 322) we presented the first of a projected series of papers by Dr. John Bryant of Boston, on the carnivorous and herbivorous types in man, and the possibility and clinical utility of their recognition. In his Shattuck Lecture before the Massachusetts Medical Society, published in the issue of the JOURNAL for June 17, 1915 (Vol. CLXXII, page 881), Dr. Joel E. Goldthwait, of this city, also selected for discussion certain other aspects of this important subject. In the present issue of the JOURNAL we take pleasure in publishing the second paper of Dr. Bryant's series, devoted to certain further

general considerations, especially with reference to the association of the various diatheses with the contrasted physical types, the evolutionary history of these types, their characteristics, and their practical relations to education, employment, insurance liability and liability to disease.

In his discussion of the relation between sex and physical type it seems that perhaps Dr. Bryant errs in suggesting that the herbivorous feminine type is more suited to child bearing than the carnivorous. As a matter of fact, we believe that the experience of obstetricians is to the contrary. It is true that the carnivorous type is probably liable to a wider variety of complications during pregnancy and parturition; yet, as a matter of experience, unaccountable dystocia seems more likely to arise in the presence of what would appear normal conditions among herbivores than among carnivores. The mere fact that on the whole the carnivorous type is outstripping the herbivorous is evidence that, under the existing conditions of civilization at any rate, nature is apparently slowly exterminating the herbivore in favor of the more easily prolific carnivore. To be sure, the increasing employment of Caesarean section offers a possibility of escape from the reproductive perils particularly affecting the herbivorous type, just as its universal adoption might ultimately affect the race as radically as did the assumption of the erect posture. Until this remote contingency, however, becomes operative, it seems that the herbivorous feminine type must, from the obstetric standpoint, be regarded as less successful and desirable of perpetuation than the carnivorous.

If an intelligent recognition and consideration of physical types be advantageous in the selection of right occupation for the individual, as Dr. Bryant suggests, it is obvious these tests must be applied with considerable special knowledge and discretion. As in all application of theories, generalization is dangerous. As a matter of fact, such recognition of type has already been applied, more or less unconsciously, by individuals for themselves and by others for them, as Dr. Bryant relates in the instance of the government service employees. Probably the selection of men for the manual and mechanical handicrafts might be more reliably made on the basis of physical type than for the professional and intellectual occupations. Such selection, however, has in the past been made with more or less rough accuracy on the basis

of phrenology, which, after all, is but a crude way of recognizing unconsciously by the head alone the physical type of the individual. For instance, it has been said that a round faced boy (that is to say, a herbivore) should be made a banker or business man, whereas a long faced boy (that is, a carnivore) should be trained as a lawyer, a physician or a teacher. Any method of selection for the professions, however, on the basis of physical type alone, is liable to overlook the important possibility, arising as a result of mixed heredity, that a human being of herbivorous type may have the kind of mind usually associated with the carnivore and vice versa. Instances of such mental and physical mixture occur with sufficient frequency to make it undesirable to apply the rule of physical type as a rule of thumb. Indeed it is doubtful if any rule should be so applied.

These observations are suggested not as contradictions, but by way of further comment on Dr. Bryant's interesting and important work. In his further study of the questions associated with the differentiation of human physical types he will be more particularly concerned with the relations of these types and of the diatheses based upon them to various clinical phenomena of medical importance in the recognition and treatment of disease. The possibility and utility of such recognition is probably even greater and presents as valuable opportunities in medical practice where physical conditions are chiefly concerned as in the determination of prospective professional efficiency in the individual.

THE DE-NARCOTIZATION OF TOBACCO.

IN the issue of the JOURNAL for August 19, we commented editorially on the possibility of the de-alcoholization of beverages as a preventive of inebriety. It now appears that a similar project is in operation for the de-narcotization of tobacco by the removal of its nicotine to such an extent as to make it practically non-toxic without destroying its flavor or pleasant properties upon consumption. The experiments to this end have been performed during the past three years at the United States Agricultural Station in Landisville, Pennsylvania.* Instead of re-

* This work has been in charge of Dr. W. W. Garner of the United States Bureau of Plant Industry.

moving the nicotine from the grown leaf, however, the method adopted is a process of cultural selection. Three years ago a number of tobacco stocks were analyzed and found to have an average nicotine content of 3.5%. The seed from the plant having the lowest content was selected and this process repeated each year. Already the nicotine content has by this means been reduced to 1.3% and it seems conceivably possible by a continuation of the process to produce a strain of tobacco which should be practically free from nicotine and, therefore, non-toxic and harmless.

If this supposition be true, it would appear that the de-narcotization of tobacco may be as practicable a possibility as the de-alcoholization of vinous beverages,—processes, which, if really feasible, should make unnecessary reforms without which the higher progress of mankind could hardly be attained.

MEDICAL NOTES.

ONE HUNDRED AND FIFTY-EIGHT LIVES SAVED IN SPITE OF HOT WEATHER.—Despite the hot weather record, the death-rate in New York City for the week ending Aug. 21 was 1.42 per thousand lower than during the corresponding week of 1914. In other words had the death-rate of the corresponding week of 1914 prevailed during the past week there would have been 1480 deaths instead of 1322, a saving of 158 lives. The death-rate for the first week was 11.88 as compared with 13.30 for the week ending Aug. 15, 1914. The following causes of death showed a decrease, to wit: digestive diseases, heart disease, tuberculosis (other than pulmonary), Bright's disease, diseases of the nervous system and violence. During the past week 348 infants under one year died, exactly the same number that died during the corresponding week of last year; but when it is considered that there are a larger number of infants under one year in the present population, it is evident that a material reduction has been effected. The campaign against mortality is surely bearing fruit. Mothers are learning how to feed, how to dress and care for their infants during the warm weather. The deaths of children under five show a slight actual increase over last year. This is due to the greater prevalence this year of several of the contagious diseases. There is a material saving in the lives of persons over sixty-five, only 188 being reported from this group as against 231 last year. The death-rate for the first thirty-three weeks of 1915 was 13.75 as compared to 14.19 for the corresponding period of 1914.

A FURTHER SAVING OF LIVES.—The death rate in New York for the week ending Aug. 22, was .63 lower than the death rate for the corresponding week of last year. This decrease amounts to a saving of seventy lives.

The total number of deaths was 1,366 with a rate of 12.27 against 1,381 deaths and a rate of 12.90 during the week ending August 22, 1914.

The deaths from sun-stroke were 75% fewer than during the third week of August of last year. The gospel of the summer hygiene is undoubtedly bearing fruit. The citizens of New York are not only learning to care for their infants properly, but likewise to care for themselves, to regulate their diet, to abstain from alcoholic drinks, to dress coolly and bathe often.

The only disease showing a noteworthy increase during the past week was typhoid fever. Six deaths more were attributed to this disease than during the corresponding week of last year and six more than during the previous week of this year.

The deaths of children under five years of age of diarrheal diseases showed a slight actual increase, but this is to be accounted for by the increased number of inhabitants in the city at this age.

Deaths from measles were fewer than during the corresponding week of last year—the first week since March 27 that the weekly death toll of this disease was lower than that recorded last year. Indeed, this decrease marks the end of the epidemic of measles that prevailed throughout the city since last winter.

The death rate for the first 34 weeks of 1915 was 13.68 as compared with a death rate of 14.16 for the corresponding period of last year.

FOOT AND MOUTH QUARANTINE.—Report from Washington, D.C., states that by an order of the Department of Agriculture, effective on August 30, the federal quarantine against foot and mouth disease was raised in Saginaw County, Michigan, Ford and Henry Counties, Illinois, and the entire state of Massachusetts. The quarantine at West Philadelphia is modified to permit the handling of cattle for export and the restricted areas are reduced in Indiana and Minnesota.

BUBONIC PLAGUE IN HAVANA.—On August 17, a case of bubonic plague was reported at Havana, Cuba, the first recorded since the outbreak in that city last winter.

TYPHOID IN BUFFALO.—Report from Buffalo, N. Y., states that, on Aug. 18, there were reported in that city 12 new cases of typhoid fever, the largest number ever recorded there in a single day.

PREVALENCE OF MENINGITIS, POLIOMYELITIS, SMALLPOX AND TYPHOID.—The weekly report of

the United States Public Health Service for August 20, 1915, states that during the month of July there were reported in Maryland ten cases of cerebrospinal meningitis, seventeen of poliomyelitis and 305 of typhoid fever. During the same period there were reported in Wisconsin six cases of meningitis, 60 of smallpox and 19 of typhoid.

SCARLET FEVER IN BELFAST.—During the spring and summer of 1915 there has been a prolonged epidemic in Belfast, Ireland, of scarlet fever, which has apparently become endemic in that city. Report on August third states that of 158 cases of infectious disease notified between June 20 and July 17, 131 were scarlet fever.

CANNING COMPOUNDS DANGEROUS TO HEALTH.—Information has come to the Department of Agriculture that the canning season has brought the usual demand on the part of housewives for salicylic and boric acid. These preparations are sometimes sold in the form of powder under various trade names and are recommended by the promoters for use in preserving canned goods in home canning. In the directions for use, the housewife is told to fill the jar with the fruit or vegetables, cover with water, and add a teaspoonful of the preserving powder. While it is true that these compounds may retard the decay of the fruit or vegetable, it is pointed out by the experts of the Department that their use may be attended by serious disturbances of health. Salicylic acid is well known as a poisonous substance, and one of the evils which may accompany its use is derangement of the digestion. It is, therefore, plain that its extensive use in food may lead to disturbance of digestion and health.

The Federal Food and Drugs Act prohibits the use of harmful preservatives in foods that enter interstate commerce. The food law of nearly every state in the union forbids the sale within the state of foods that have been preserved with harmful substances. Neither the federal or state food laws apply to foods that are canned in the home and consumed there. It would seem, however, that the housewife would not knowingly use, in the foods she provides for her family, substances that she could not use in foods for sale without violating the law, because these substances are injurious to health.

Fruits and vegetables can be kept indefinitely if they are sterilized by heat and properly sealed, and there is no excuse, in the opinion of the experts of the Department, for running any risk by using preserving powders, which may be injurious to health. The use of such powders in addition to the possible injury to health, encourages uncleanly or careless work in canning. Reliance is placed in the efficacy of the preserving compound instead of upon cleanliness and heat.

The Department has issued bulletins that give specific directions for the preserving and canning of fruits and vegetables without the use of preserving powders or canning compounds. These bulletins may be obtained without cost from the Department of Agriculture.

COMPLETION OF CINCINNATI HOSPITAL.—After about four years spent in construction, the new Cincinnati Hospital is ready for occupancy. It was planned by a special commission of physicians who arranged that it should incorporate all that is desirable in modern hospital building. Its total cost was about \$4,000,000. It occupies 65 acres of land and is made up of 45 wards containing 900 beds. The department of contagious diseases is a separate hospital, having its own wards and administration building. The spacious grounds have been utilized for tennis courts, baseball grounds and parks.

PANAMA-PACIFIC DENTAL CONGRESS.—On September 9, there came to a close the Panama-Pacific Dental Congress which has been in session since August 30, at San Francisco, with an attendance of 5,000 members from every state in the Union and 26 foreign countries. A total of 175 papers was presented at its meetings.

AMERICAN VETERINARY MEDICAL ASSOCIATION.—The fifty-first annual convention of the American Veterinary Medical Association was opened on August 30, at Oakland, Cal. The principal subject of discussion was the control of foot and mouth disease.

NATIONAL EDUCATIONAL ASSOCIATION.—On August 17, at the annual convention of the National Educational Association held in Oakland, California, a paper on "Child Welfare and Rural Schools," was presented by Dr. Thomas D. Wood of Columbia University, New York City, who pointed out that of the 20,000,000 school children of the United States about one-half are in attendance at rural schools. It is surprising that these children are less healthy and present more physical defects than city school children, including those of the slums.

The rural school, from the standpoint of health and general fitness for its important use, is the worst type of building in the whole country, including not only all types of buildings used for human beings but also those used for livestock and all domestic animals. Rural schools are on the average less adequate for their use than prisons, asylums, almshouses, stables, dairy-barns, pigpens, chicken houses, dog kennels.

Necessary provisions for the welfare of rural school children should include the following:

"(a) Sanitary and attractive schoolhouses and grounds.

"(b) Teachers better trained and better paid.

"(c) Health examinations, including dental inspection, once a year.

"(d) Health care in the schools including health instruction, warm school lunches, tooth brush drills and training in all health habits.

"(e) Correction of injurious physical defects by school doctors, health clinics, district nurses etc.

"(f) Coöperation of all available agencies for promotion of health and welfare of country school children."

ALLEGHANY GENERAL HOSPITAL.—It is announced that the children of the late William H. Singer of Pittsburgh, Pa., will erect, equip and endow, in his memory, at a cost of \$400,000, a laboratory in connection with the Alleghany General Hospital for investigations into the origin of disease.

EUROPEAN WAR NOTES.

CHOLERA IN AUSTRIA.—Report from Zurich, Switzerland, by way of London, on August 24, states that on August 19, there were in Austria 1566 cases of Asiatic cholera.

A CASE OF CARDIAC SURGERY.—In a recent issue of the *Revue Scientifique* is described an unusual case of cardiac surgery reported before the French Academy of Medicine by Dr. Beaussant, an army surgeon. The patient, a sergeant in the French army, was struck on October 1, 1914, at Saint Hubert, in the Argonne, by a fragment of a hand grenade, which pierced the abdominal wall, diaphragm, pericardium, heart muscle, and lodged in the cavity of the right ventricle. The original wound healed, but the presence of the foreign body was revealed by x-ray. On February 17, 1915, the fragment was removed by direct incision through the cardiac wall. It was found free in the ventricular cavity, whence it was withdrawn with forceps. It measured $\frac{3}{8} \times 1\frac{1}{4}$ inch, and weighed 1.5 grams. Convalescence was complicated by angina, slight pyrexia and pleuritis; but the sergeant recovered and was returned to duty on March 17. This case is considered probably unique in the duration of time that the fragment remained in the heart.

THE STERILIZATION OF DRINKING WATER.—It is reported that Drs. Vincent and Gaillard of the Academy of Medicine, Paris, have, after repeated experiments, succeeded in perfecting a method whereby the drinking water of the French soldiers may be rendered free from pathogenic germs. A tablet of three to four milligrammes is made up of hypochlorite of lime and common salt in proportion of fifteen milligrammes of the former to eight centigrammes of the latter. This tablet is sufficient to sterilize one litre of water in fifteen minutes' time. In consideration of the difficulty of the army to provide safe drinking water for its soldiers under all circumstances, this convenient and simple method has much to commend it.

PESTILENCE IN BELLIGERENT COUNTRIES.—During the week ended July 17 one fatal case of typhus fever was reported at La Rochelle, France, and five cases of Asiatic cholera in Silesia, Germany. During the week ended June 12 seventy-five cases of cholera were reported in Moscow, Russia. One case of cholera occurred at Trieste, Austria, on August 7, and on August 11 one case at Livorno and three at Venice, Italy.

HONORS FOR DR. RYAN.—It is announced that Dr. Edward W. Ryan, of Scranton, Pa., chief of the American Red Cross at Belgrade, has been decorated by both the French and the Serbian governments for his work during the suppression of the recent typhus fever epidemic.

A PHYSICIAN'S GAS HELMET.—It is announced that Dr. Chumey McPherson, of Newfoundland, who went to Europe with the first contingent of volunteers from that island, has devised a new protective helmet for defense against poisonous gases. It consists of an ordinary Balaklava cap, of khaki, to which are attached a pair of celluloid goggles to guard the eyes, and a mouth pad saturated with a solution of soda and potash.

SUMMER WORK FOR FRENCH HOSPITALS.—The French Wounded Emergency Fund reports that since May the New England headquarters have helped 432 French hospitals containing 56,000 beds. Each week a shipment of surgical supplies has been shipped to England for the use of the smaller French hospitals. These cases contain surgical dressings among other things, great numbers of which have been made up at various summer resorts by vacationists. Branches are established at Islesford, Me., by Mrs. O. Y. Bowditch; Rockport, by Mrs. W. C. Rives; South Duxbury, by Miss Louise Coburn; Portland, Me., by Miss Irene H. Noyes; Round Pond, Me., by Mrs. William De Lancy Howe. Mrs. Howe has also formed a tentative organization in Friendship, Me. At Seal Harbor, Me., Mrs. William T. Sedgwick of Boston, and Mrs. Edward K. Dunham of New York, have been active in forming a committee of women to superintend the carrying on of the work. The sterilization of the bandages has been done at the Massachusetts General Hospital, Boston City Hospital, Peter Bent Brigham Hospital and the Homeopathic Hospital.

BELGIAN RED CROSS HOSPITAL.—In the issue of the *Lancet* for August 14, is a description of the Belgian Red Cross base hospital at Calais, established by Dr. De Page at the close of 1914 in the buildings of the Institut Jeanne d'Arc, under command of Captain Neumann of the surgical institute of Namur.

"From the Rue Champallier a big *porte cochère* gives into a courtyard; directly on the left is the guard-room, with medical officers' quarters above, and on the right, where were formerly

the school teachers' quarters, the building has been transformed into an operating theatre, sterilization department, and instrument and bandage room, with the dispensary above. Beyond this courtyard in the grounds is the hospital, a long lofty building divided into wards holding from 7 to 12 beds each. On the ground floor are the wards for men and the dining room for the staff and nurses, these latter, it is interesting to note, being nearly all drawn from the British Red Cross Society. The first floor is taken up by an isolation ward and the officers' ward, while the floor above, one long vast *salle*, is given over to the convalescents who are waiting to be transferred to the South of France or to England. Annexed to the ground floor is the chapel, which has been transformed into a linen room; there is also an excellent radiographic and radioscopic installation."

A Ford motor ambulance has been presented to this hospital by Harvard University students.

WAR RELIEF FUNDS.—On September 4, the totals of the principal New England relief funds for the European war reached the following amounts:—

Belgian Fund	\$271,461.37
Polish Fund	50,222.55
Serbian Fund	36,624.55
French Fund	9,430.18
Italian Fund	2,603.10

BRITISH PRAISE FOR AMERICAN RED CROSS.—A report from the British Red Cross in Serbia, recently received and published by the *London Lancet*, speaks in high terms of praise of the work of the American Red Cross in that country.

"The work of the Americans already challenges comparison with what the British workers have done and it promises soon to outstrip us. An international sanitary commission, of which Sir Ralph Paget is chairman, has been established with headquarters at Nish. Under it the general medical and sanitary work of the country has been roughly apportioned between the different coöperating nations. France has charge of the northern half of the country and the United States of the south. Nish and its immediate neighborhood is under the Russians. The British have had the care of the army and most of the hospital work, except what the Serbians themselves are doing.

"This plan is working smoothly and well, but the share of the burden which the United States is bearing continually increases and will increase. Dr. Richard Strong, head of the American sanitary commission, is an exceptional man of wide experience and he has behind him the practically unlimited financial resources of the wonderful Rockefeller foundation.

"The United States, moreover, is the only nation which at the moment can spare an almost limitless supply of doctors. A party of 25 additional American doctors is expected shortly at Salonika. They are the advance guard of a

contingent of 150 or more. As they land they will be detached, singly and in twos and threes, to points all over Serbia where they are most needed.

"The typhus has now been reduced to such comparatively trivial proportions that one almost begins to speak of it in the past tense, although there will be many thousands of deaths from it yet. The total number during the winter and spring was well over 200,000.

"There are now 420 British doctors and nurses in Serbia. There have been no new wounded for some five months; typhus and typhoid have declined until they are no longer a serious public menace, and cholera, however anxiously awaited, has not yet arrived."

BOSTON AND NEW ENGLAND.

REOPENING OF BRIGHTON STOCKYARDS.—As a result of the raising of the federal quarantine for foot and mouth disease, noted in a preceding column of this issue of the *JOURNAL*, the stockyards at Brighton, Mass., were reopened on August 30 for the receipt and sale of cattle from Maine, New Hampshire, Vermont and Massachusetts.

NEEDS OF BOSTON FLOATING HOSPITAL.—On August 17, the Boston Floating Hospital issued an appeal to the public for \$20,000 urgently needed for the successful completion of its present season's work. On August 31, only \$9,549.58 of this sum had been subscribed. It is earnestly to be hoped that generous contributors may speedily make good this deficiency.

HOSPITAL BEQUESTS.—The will of the late Calantha E. Marsh of Boston, which was filed on August 31, in the Suffolk county registry of probate, contains bequests of \$1,000 each to the Massachusetts Homeopathic Hospital, the Kindergarten for the Blind, and the Industrial School for Crippled and Deformed Children.

PREVENTION OF MALARIA.—Professor Selskar M. Gunn of the State Department of Health, has issued a statement regarding the prevention of malaria, its prevalence, causes and proper precautionary measures to be taken. Because of the abundance of mosquitoes bred during the summer, malaria has been more than usually prevalent, seventy cases having been reported since the first of May. The statement continues with a description of the habits of the anopheles mosquito, methods of destroying its breeding places and the proper protection of houses by suitable screening. Daily doses of quinine taken during the malaria season, to prevent attacks of the disease, are urged.

FOXBOROUGH STATE HOSPITAL.—The recently published annual report of the Foxborough State Hospital records the separation of the patients and the removal, in June, 1914, of those

addicted to drugs, and inebriates, to the Norfolk State Hospital. In October, 1914, its new superintendent, Dr. Albert C. Thomas, assumed the administration of the hospital with Dr. George E. McPherson as first assistant physician. The number of patients remaining in the institution September 30, 1914, was 203. There had been 18 patients dismissed during the year.

ENTERIC FEVER FROM FRANKLIN PARK WATER.—It is reported that 12 cases of febrile enteric disturbance have recently occurred in this city among persons who, at a picnic, on July 25, drank water from a pool in Franklin Park. Investigation is being made by the Boston Health Department as to the nature and source of the probable infection.

TYPHOID FEVER IN PROVIDENCE.—Report from Providence, R.I., August 21, states that 35 cases of typhoid fever have recently occurred among residents of the Olneyville section of that city. All are among families supplied by two dealers whose milk is therefore believed to be the source of the infection.

INFECTION FROM SODA GLASSES.—In the effort to prevent possible spread of infection from unclean utensils at public soda fountains, the Boston Health Department has recently issued the following notice and regulation:—

“Proprietors of drug stores and other places where ice cream, college ices, etc., are sold are hereby notified that it is hereafter required that spoons, glasses or other utensils used in serving such ices be thoroughly cleansed and dried after each use.”

Miscellany.

HEALTH TEMPLES IN ANCIENT GREECE.

THE subject of the health temples of ancient Greece is one of perennial interest which, at various times, has been dealt with in preceding issues of the JOURNAL. As a matter of fact the medical knowledge of Egypt preceded that of Greece, as did its civilization, but the records which remain of Egyptian medicine and medical worship are relatively fragmentary. It seems indubitable, however, that the early Greeks fully recognized their indebtedness to Egyptian methods and knowledge. It may be recalled that in the fourth book of *Odyssey*, when Helen mixes an opiate in the wine at the feast, reference is made to her having obtained knowledge of such drugs from the Egyptian princess Polydamna, wife of Thome. And of the Egyptians, Homer goes on to say (*Il.* 231-232):

ἰγτροὶ δὲ ἕκαστος ἐπιστάμενος περὶ πάντων
ἀνθρώπων ἧ γὰρ Παιήονός εἰσι γενέθλης

In a paper read before the section of history of medicine of the Royal Society of Medicine on December 17, 1913, and published in the issue of the *Lancet* for January 10, 1914, Dr. Richard Caton presented a careful study and description of several of the ancient Greek temples and of the ceremonial rites there practised. The first of these temples, that of Amynos, has been largely forgotten, and in Greek literature, indeed, is mentioned only in the writings of the Christian Eusebius. Amynos was an Athenian god of healing, whose cult has been discovered within a few years, his name being derived from the word ἀμύνειν to ward off, to protect. At the time of Professor Dörpfeld's excavations at Athens in the region between the Areopagus and the Pnyx, there were exposed, among other relics, the ruins of the Amyneion, or temple of Amynos, an irregular area bounded by a wall with foundation of hard blue limestone and having at its eastern side a temple or chapel, in the center of which is an altar and sacred well. Many inscriptions were found here and an attempt has been made at a restoration of the precinct, grove and ancient temple.

“Its date is best judged by the pottery. Attic black figured, proto-Corinthian of 700 B.C., and lowest of all Greek geometrical pottery of 900 or 1000 B.C. were found. The temple at that date would have a stone foundation with walls of sun-dried brick covered with cement. The colonnade and pediment, if existing, must have been of wood, the columns formed of rough pine trunks. No stone drums of column nor any parts of a stone frieze have been found. Many inscriptions of later date were discovered. The cult of Asklepios came to Athens about 420 B.C. Inscriptions are mostly to Amynos and Askepios, and sometimes to them and Dexion (Sophocles). Fragments of marble snakes are found, and numbers of remains of sculptured figures and ex-votos.

Asklepios seems to have been quite secondary to Amynos in the shrine, and up to Roman times Amynos holds his pre-eminence. Was incubation practised here? We have no information. A second foundation has been found which possibly was the wall of a shed for incubation. Nor is anything known about baths, drugs, or methods of treatment. But treatment seems to have been greatly valued, if we may judge from the inscriptions and ex-votos.”

Another of the ancient Greek deities of healing was Amphiaraos, whose chief sanctuary was near Oropus in Attica. He had also subsidiary shrines at Rhamnus, Argos and Sparta. Dr. Caton describes his temple as follows:—

“In a pleasing glen, well clothed with pines, planes, and oleanders, through which a stream flows and in which many nightingales lift their voices, the shrine was built. Amphiaraos, a son

of Melampus or Apollo, was a prehistoric warrior and a hero, one of the Seven against Thebes and one of the Argonauts. When flying from his enemies the earth opened near Oropus and swallowed up Amphiaraus and his chariot. Why he should have become a great healing god it is hard to say.

"On the northwest of the stream on a flat strip of ground stand the remains of the sanctuary. Most to the west are the ruins of the Temple of Amphiaraus, a building 95 feet long and 43 wide, having a broad columned portico at the east end, six columns between antae. The cella had three aisles, separated by rows of columns. At the southwest end was apparently a small porch 8 feet by 5. A large square base stood near the centre of the cella, on which, no doubt, stood the great image of Amphiaraus—part of a colossal arm found was doubtless part of the figure—it was rather nearer the eastern end than the west. Probably the temple was not hypaethral, for if so rain would fall on the god; louvres more probably lighted the cella. In front of the temple stood a large altar 28 feet long and 14 broad, built of limestone. It was dedicated to several gods. Three long curved steps are seen on the north of the altar, on which no doubt worshippers stood or sat. The sacred spring rises a few feet south of the altar, and was used for special purposes only (not for washing hands nor for purification). Amphiaraus rose as a god from this spring—hence its sanctity. North of the temple and altar stood a large number of pedestals bearing statues.

"Northeast of the temple is a large stoa 360 feet long and about 36 wide. It has an open Doric colonnade of 49 columns on the southeast side, the other sides having solid walls. At each end is a chamber about 24 feet wide, and between them a long space of 310 feet (gratings in separation walls). A central line of 17 Ionic columns divided the stoa into two aisles. A marble bench ran along the back wall. The inner face of the wall was stuccoed and painted. Traces of painting still remain. This was the abaton, enkoimeterion or ward; the women occupied the western end, the men the eastern. Behind the colonnade, excavated from the hill side, is the theatre, with circular chorus space about 40 feet wide. The stage was about 40 feet by 20. Northeast of the abaton or ward is a series of bath-rooms, ten in number, dating from the third century B.C., but Roman alterations are evident. Two rooms have a hypocaust. Men and women had separate rooms.

"The inscriptions indicate that the sanctuary was founded at the end of the fifth century B.C., and that it was closed during winter. The priest was obliged to be present not less than ten days in each month and never to be absent more than three days at a time. The nakaros or saceridan was to attend regularly to his own duties. Any patient misbehaving might be fined five drachmas. On admission each patient paid a fee of not less than nine obols. The priest,

when present, must pray over the victims and put their flesh on the altar. The shoulder of every animal sacrificed, and in some cases both shoulders, were given to the priest, also the skin was ultimately his property. The patients might eat most of the flesh of the sacrificed animal, but no part of it might be taken beyond the precinct. The nakaros wrote down all the names and addresses of the sick. Before incubation each patient sacrificed a ram, and he used its skin as a bed, lying upon it in the abaton. Then incubation commenced, and he nightly awaited dreams and visions of the god.

"Whether or not any drugs were given, no one knows. A special diet with occasional abstinence was enjoined—fasting from all food for one day and from wine for two. No beans were allowed. When recovery took place the convalescent dropped gold or silver coin into the sacred well (which offering presumably was subsequently abstracted by the priest). Models in gold or silver of the diseased organ or limb were suspended in the temple near the figure of the god. Many gold and silver vessels and ornaments were given. There was a festival of the god every fourth year. That is all that is known.

"The shrine of Trophonios of Lebadea near Thebes had a lesser vogue for cure of the sick. The methods were somewhat the same: incubation and sleeping on the skin of a black ram."

The worship of Asklepios probably began to develop about 800 B.C., and extended from its original source at the Thessalian town of Tricca* to its great centers in Cos and Epidaurus. In the fifth century before Christ it had become established at Athens and Corinth; later it extended to Pergamon in Asia Minor, and finally, in 270 B.C., was brought to Rome and established there in a temple on an island in the Tiber. Dr. Caton describes as follows the great temple at Epidaurus in Argos near Athens:—

"The site of the Hieron was six miles inland from the town of Epidaurus. At the time of its greatness an extensive precinct occupied the beautiful valley extending from the hill Titthion, where Asklepios was suckled by a goat, to Kynortion, on which stood the Temple of the Maleatean Apollo. Here is a rough bird's-eye view of the precinct as seen from the south—a splendid array of temples, stoa, a great theatre, a stadium and grove. Here is the gateway with well for ceremonial purification, and the northern boundary wall. Here is the central temple of Asklepios, built in the fourth century B.C. The eastern facade presented a richly decorated and colored scheme. The eastern pediment represents a combat of Greeks and Amazons, the western a conflict with Centaurs—Victory on the apex, and Nereids as aeroteria; an elaborate ivory door. A side view of the temple shows the works of art adjacent to it, and behind it a part

*Cf. Homer's *Τρίκλῃς ἐξ ἱπποβάτοιο* (Iliad IV, 202).

of the abaton. A sketch of the interior shows the splendid gold and ivory figure of the god with a golden serpent and a temple dog. Chryselephantine sculpture is very beautiful; the ivory, however, tended to crack, as was found at Athens and Olympia. But this great figure of Asklepios never required to be moistened with oil or water, as did the others, for the god of physic we may presume knew how to preserve his own integument. Only the floor of this temple and fragments of its decorations remain.

"The abaton, or enkoineterion, or hospital ward was employed probably half for men and half for women. On the south it has an open colonnade. So whatever other therapeutic agencies were employed there is no doubt that pure fresh air was enjoyed by the sick who occupied it. At the west end it was two stories in height. Here incubation took place, the sick awaited the personal aid of the god or of the serpents, or they hoped for dreams or visions guiding them as to the best treatment for their several ailments.

"Here is the Tholos or Thymele, an extraordinarily beautiful building of white marble colored in parts. It was the most splendid circular building ever erected by the Greeks, dating from the third century B.C., built by Polykleitos the Younger. It was Doric externally, Corinthian within. Within were two celebrated paintings, Methe (drunkenness) and Eros, suggesting the relation of Dionysos and Aphrodite to the ailments which afflict mankind. There are various opinions about the function of the Tholos. Some think it was the sacred well. The foundations are curious, a dark labyrinthine basement, which I think cannot have been a water-tank, because, first, it was not cemented and would never have held water; secondly, there is no spring nor conduit leading to it; thirdly, the word Thymele means a sacrificing place; and fourthly, Pausanias speaks of the Tholos and the sacred well as entirely distinct. I have little doubt that it was the home or lair of the sacred serpents; in the vaults beneath they dwelt and bred in numbers, and from here they were sent to the numerous asklepieia all over the ancient world. The snakes would ascend to the floor of the tholos, where bloodless sacrifices were offered to them, and where the sick gave them the honey cakes, popana, and other sacrificial delicacies they were fond of."

Of the ceremonial rites observed in these Greek medical temples, Dr. Caton presents an interesting discussion. Vast numbers of the sick came to them from all parts of the world and were presumably lodged in tents, except while they were receiving treatment, when they slept in the abaton. Thousands of well persons, however, came to these religious festivals merely for curiosity and enjoyment, like the throngs who go nowadays to such religious festivals as those of the Grotto at Lourdes, whose ceremonies and purposes are in many respects closely analogous to those of ancient Greece. Many

characteristic tales are narrated in connection with these occasions, of which but one must serve as an example. The story is told of Hermon, of Thosos, who was blind and came to Epidaurus for cure.

"His sight was restored by Asklepios, but Hermon did not send the fees he had promised on his return home, so the god again made him blind. He came back to the hieron with the fees and was again cured. A man had an abscess in the abdomen. In a dream the god ordered his servants to hold him while he (Asklepios) opened the abdomen, cleared out the abscess, and sewed up the wound. When the patient awoke a great pool of blood was on the floor of the abaton, and he was cured. A great number of such inscriptions were fixed on the wall of the abaton.

"In later times superstition had a less share and science a greater one in the work of healing. We read of the priests using reasonable and useful methods of treatment: diet of a plain and simple kind, hot and cold baths, poultices, various medicaments such as hemlock juice, oxide of iron, hellebore, squills, lime-water, and drugs to allay pain, active gymnastic exercise, friction of the skin, and counter-irritation. Bleeding was practised, as shown in this vase-painting, and surgical methods were in use, for reliefs of surgical instruments exist."

Interesting contemporary records are preserved in literature of the functions and ceremonies practised in these Greek medical temples and of the sacrificial rituals employed. An excellent example of this type of literary composition may be found in "The Sacrifice to Asklepios," a mime of Herondas, a translation of which was published in the issue of the JOURNAL for January 9, 1913 (Vol. clxviii, p. 46).

THE HISTORY OF BLOOD-LETTING.

IN the first Mellon lecture, delivered at Pittsburgh, Pa., on Feb. 27, 1915, and published in the issue of *Science* for July 30, Prof. John J. Abel sketches the history of blood-letting, in part as follows:—

"In the latter part of the twelfth century, when universities, as we now know them, were coming into existence, there originated in the School of Salerno the 'Regimen Sanitatis Salerni' or 'Code of Health,' a poem written in Latin hexameter verses and giving the medical notions of the day, as derived from the Arabic writers, in regard to blood-letting, diet and personal hygiene. The high value placed on the 'Regimen' may be seen from the fact that it passed through some 240 different editions and was translated into all the known languages. In general praise of blood letting the poem says

"Bleeding the body purges in disguise,
For it excites the nerves, improves the eyes
And mind, and gives the bowels exercise,
Brings sleep, clear thoughts, and sadness drives
away,
And hearing, strength and voice augments each day."

"Other verses give directions as to what months are proper and what are improper for bleeding, tells what diseases are benefited by blood-letting and in what quantities blood should be drawn, and the effect of age and other circumstances.

"Acute disease, or only so in part,
Demands blood-letting freely from the start.
In middle age, bleed largely without fear,
But treat old age like tender childhood here."

"In the sixteenth and seventeenth centuries there were heated controversies between advocates of the Hippocratic method of letting blood near the diseased part, and those of the Arabian method of opening a remote vein. Among the former was Pierre Brissot (1478-1522) of Paris, and among the latter Leonardo Botallo, a Piedmontese, an eminent practitioner of his time, "chief physician to Charles IX, advising venesection to the limit, regardless of the nature of disease, the age or condition of the patient. Blood-lettings of three to four pounds each, repeated as often as four or five times, were advised, says Haeser, and this historian adds that the explanation of this 'Vampyrismus' is probably to be found in the circumstance that Botallo lived in Northern Italy, where diseases of an inflammatory character were prevalent, and more especially that in his experience as an army surgeon he encountered only patients of the most robust type. Botallo, in defending his practise said,

"The more foul water is drawn from a well, the more good water can flow in to replace it."

"An ardent follower of Botallo was Riolan the younger, who falls back upon Hippocrates and Galen and lays down the rule that one must take away as much blood as possible in every disease. As an adult is judged to have about thirty (!) pounds of blood, the tapping of half this amount, or fifteen pounds, in the course of fourteen days would be about the right amount to take, says Riolan. Guy Patin (1602-1672), himself an ardent bleeder and purger, informs us that Bovard, body physician of Louis XIII, bled that monarch forty-seven times, gave him 312 clysters and prescribed emetics and purges, 215 times, all in one year.

"A little later, that able and credulous Belgian mystic and follower of Paracelsus, J. B. Van Helmont (1578-1644), an iconoclast in general, called by his admirer Haeser 'The fist of the seventeenth century,' went so far as to condemn venesection entirely."

Franciscus de la Boë (1614-1672) of Leyden advocated moderation in venesection. In the chapter of his "New Idea" (translated by Rich-

ard Gower, of London, in 1675) on the motion of the blood through the lungs, he says:—

"A *Plethora of Blood* is soon and safely cur'd, by a sufficient *Emptying* of it by *opening a Vein*; whether it be together and at once, or by repeated turns, according to the peculiar nature and strength of the *Sick*. For there are many who cannot bear to have much taken away together, but soon fall into a *Swooning*: by which feeling none can at any time receive any good, I had rather that it should be prevented, as often as may be, and every Cure be done securely rather than rashly, seeing it often happens to those rash Blood-Letters, that they educe Life together with Blood."

"An instance of lavish blood-letting in a medical crisis may be found in the experience of that adventurous spirit, Thomas Dover, to whom we owe the much used 'Dover's powder.' In 1708, Dover, then forty-eight years old, set out on a privateering expedition, and was given command of a ship, the *Duke*, while his superior, Captain Woodes-Rogers, took command of the other ship of the squadron, the *Duchess*. The three years' voyage of these buccaneers is of interest historically because,

"touching at the island of Juan Fernandez, they took on board Alexander Selkirk, who had lived alone on the island for four years and four months, and whose story was to develop in the skilful hands of Defoe into that of the immortal 'Robinson Crusoe.'"

"In Dover's 'Ancient Physician's Legacy to His Country' we find the following interesting passages:—

"When I took by Storm the two Cities of Guayaquil, under the Line, in the South Seas, it happen'd, that not long before, the Plague had raged amongst them. For our better Security, therefore, and keeping our People together, we lay in their churches, and likewise brought thither the Plunder of the Cities.

"In a very few days after we got on board, one of the Surgeons came to me, to acquaint me, that several of my men were taken after a violent Manner, with that Languor of Spirits, that they were not able to move. I immediately went among them, and, to my great Surprise, soon discerned what was the Matter. In less than Forty-eight Hours we had in our several ships, one Hundred and eighty Men in this miserable condition.

"I order'd the Surgeons to bleed them in both Arms, and to go round to them all, with Command to leave them bleeding till all were blooded, and then come and tie them up in their Turns. Thus they lay bleeding and fainting, so long, that I could not conceive they lost less than an hundred Ounces each Man.

"If we had lost so great a Number of our People, the poor Remains must infallibly have perished. . .

"We had on board Oil and Spirit of Vitriol sufficient, which I caused to be mixed with Water

to the Acidity of a Lemon, and made them drink very freely of it: so that notwithstanding we had one hundred and eighty odd down in this most fatal Distemper, yet we lost no more than seven or eight; and even these owed their Deaths to the strong Lignors which their Mess-Mates procured for them. . . Now if we had had Recourse to Alexipharmicks, such as Venice Treacle, Diacordium, Mithridate, and such-like good-for-nothing Compositions, or the most celebrated Gascoïn's Powder, or Bezoar, I make no Question at all, considering the heat of the Climate, but we had lost every Man."

"Of non-medical literature the Satire of Gil Blas, written early in the eighteenth century, but in reality giving a picture of seventeenth-century excesses in blood-letting, is worth citing.

"Dr. Sangrado is called in to prescribe for a gouty old canon, and he at once sends for a surgeon and orders him to 'take six good porringers of blood in order to supply the need of perspiration.' The surgeon was ordered to return in three hours and take as much more, and to repeat the evacuation the next day. The patient was 'reduced to death's door in less than two days,' and, the notary being summoned to make the will, seized his hat and cloak in a hurry, when he learned from the messenger, Gil Blas, that Dr. Sangrado was the physician. 'Zooks,' cried he, 'let us make haste, for the doctor is so expeditious that he seldom gives the patient time to send for notaries; that man has choused me out of a great many jobs.'

"But the misuse of bleeding continued in the centuries following, and at no time was the practice more abused than in the latter part of the eighteenth or even in the first five decades of the past century. French and Italian authorities, especially, were great believers in blood-letting. Broussias (1772-1832) is said to have used 100,000 leeches in his hospital wards in one year. This physician and his follower, Bonilland, actuated by false theories of the causes of fevers, recommended the bleeding of a patient 10 to 12 and even 20 times in the course of treatment."

Correspondence.

PARIS LETTER.

BRIEF IS THE MEMORY OF THE EARTH!

(From Our Special Correspondent.)

PARIS, July 17, 1915.

Mr. Editor: I went out a short time ago to see a portion of the ground over which was fought the battle of the Marne, and I must confess that the experience was a good deal of a disillusion to me. That the memory of man is short, has in all likelihood been a proverb ever since the world has been inhabited; but that the memory of the earth was equally transitory, came to me as a considerable shock.

Between Vareddes and Meaux, about 50 kilometres due east from Paris, the Marne makes a huge loop to the South, the region between the two places being a

high, rolling plateau: this point formed the angle that the German centre made with their flank which was being driven in by the army under Maunoury which General Joffre had assembled, unbeknown to the enemy, behind the screen of the Paris defences. General Joffre's strategy at this period was really admirable. In the early encounters of the war the French were pretty badly hustled about,—there is no gainsaying that fact; but then, instead of letting everything go to pieces, this wonderful man conceived the idea of his stupendous but thoroughly-reasoned-out retreat which drew the foe into a species of lobster's claw, one point being Paris and the other Verdun, from which he only barely escaped when the two branches began to close in. There can be no doubt that when this feat has been thoroughly examined, and the circumstances are well taken into consideration, General Joffre's strategy under such very serious conditions will go down in history as one of the great accomplishments of the art of war.

Poor Maunoury, by the way, was later on the victim of one of the most extraordinary accidents of the war: he and a brother general were one day looking through a loophole at a perfectly quiet point of the trenches when they were both shot through the head by a single bullet, he losing one eye outright, and, it is apprehended, the sight of the other,—his colleague being wounded in the forehead. The latter has now entirely recovered and has resumed his duties again.

Leaving Meaux the carriage takes you up an interminable hill in order to reach the high plateau, and once there you have the classical, fertile French landscape in its deep-green spring verdure: waving crops, half grown; dense masses of trees; bright, white, poplar-bordered *chaussées* leading off to villages here and there,—it is all smiling, prosperous and peaceful, the scene you have admired scores and scores of times in this beautiful, well cultivated land. Here is a farm partly burned down; but any fire could do as much as that. That church over at Barey looks a bit earthquakey; but it is too far off to distinguish details as yet. The grain is about knee-high, and all the fields seem to be in full cultivation; how about the entire manhood being away under arms! *This* the battle of the Marne? Evidently some more of our preconceived ideas will need readjusting.

I may as well tell the patient reader who has been able to get through my war-strategy, and description of landscapes, that if anyone here advises him to go and visit the battlefield of the Marne he had better merely stay in town and take his coffee at the Café de la Paix, for all the battle-field he will see. At two places the little white crosses that mark the temporary resting-places of the dead are sadly plentiful; but when you have seen one cross you have seen them all. The Barey church is badly battered, the village walls are closely pitted with rifle shots, the cemetery at Chambry has a line of loopholes above its long row of new-made graves,—and that is about all! Eight months ago history was being written on this plateau with a broad and generous hand. From what I have said, and shall say in a moment, it is clear that in those early days of September, when we in Paris had that peculiar sensation of emptiness about our solar plexus and were dropping our weight at the rate of a pound a day (I have now collected quite a number of instances of men who simply *melted* in Paris during that strain, from sheer apprehension!), the general conditions upon this high ground back of Meaux were very far from conducive to longevity. But kindly Nature has intervened, and has drawn her soft mantle of green over the whole of it; and by next spring the honored dead will all have been exhumed and transferred to their proper resting places, the walls will then have been replastered, and the poor Barey church probably rebuilt. What will there remain by that time to speak to the passer-by of this struggle of giants? Not much,—but still something: a reminiscence that will last a long, long while.

One of the most striking object-lessons in the New

York Museum of Natural History is a section of a big sequoia tree, well over a thousand years old, as I remember it, on which the annual rings are marked with little flags indicating that when the tree was that large such and such an event occurred: the birth of Mahomet, the conquest of England, the discovery of America. Well, strange to say,—outside of the church burial-places, it will be the trees of the *chasseurs* from Meaux to Varedes that alone will bear witness to this battle in the times to come. Up on the brow of that hill, at the highest point, the road is bordered on either side by a row of unusually fine trees of from one to two feet in diameter,—really big trees. This must have been a particularly hot corner during the fight, for all of these trees are riddled; and not with bullets,—a bullet would hardly show on a tree, it only shows on a plaster wall because it splits off a large flake,—but with shell. Some missiles took out a big piece from the tree-side, others went smack through, while still others carried away an entire branch or even cut the tree-stem clean off! But the trees are growing once more, cheerfully, and as though nothing had happened, and will for many a long year to come give evidence to the younger generations, as they walk out there Sunday afternoons, of the deeds of their fathers during the great war. All the same, it is rather startling to think that that is all that will remain of this terrific struggle! Wounds must heal, both physical and mental, otherwise life would be intolerable; but it is rather a shock, to see them heal as quickly as this!

Speaking of the graves of the fallen, brings me to another remarkable feature of this war, the extraordinarily high ratio between killed and wounded,—something quite unprecedented. When the papers were reporting the British casualties at Neuve-Chapelle, I was horrified to see that among the thousand odd officer casualties there were 350 killed, over one-third, and this did not include the missing, among whom there must have been still more killed. I thought that an explanation of the fact might lie in the circumstances that the British officer is an absolutely reckless creature, who always starts off well ahead of his men, and seems to consider that his special rôle in life is to get himself picked off by the enemy's sharpshooters. This, by the way, is a point that will certainly have to be changed in future wars; it is as clear as day that a country that wishes to keep any officers at all for further use will have to devise some other way for them to direct their men than the present one, which is nothing less than a thinly disguised form of *haru-kiri*.

The French have never published any collective casualty-lists; but a while ago, quite a time back, I saw what looked like an authoritative estimate, giving 400,000 killed and 750,000 wounded,—almost the exact ratio of the officer-casualties above cited! Quite recently, only a few days ago, Mr. Asquith reported in the House of Commons the British casualties to date, in which the same awful ratio appears,—in round numbers: officers, killed 3,300, wounded 6,500, missing 1,100;* men, killed 47,000, wounded 147,000. The ratio for the men is not quite so high, nearer one-quarter than one-third; but it should be noticed that there are reported in addition 52,600 men missing, a very large part of whom are certainly killed, as the Germans do not claim half that number of British soldier-prisoners. These figures are certainly new in warfare, and bear fearful testimony to the efficacy of modern weapons. And if this is the ratio among the Allies, who fight in extended formation and with a steady view to economy of life, what must the figures be among the Germans, who, especially during the early stages of the war, were absolutely reckless in their expenditure of men!

In connection with the curious accident whereby two generals were put out of action by a single bullet, let me mention another very peculiar occurrence of this

war. It was reported in the daily press, with regiment, name, place and hospital, and has every appearance of truth. A soldier, Boissay by name, entered the ambulance for a fracture of the left leg and wounds of the right. X-ray examination revealed in the latter round bodies that were taken for shrapnel bullets, but that were found on extraction to be *three twenty-franc gold pieces*, or Napoleons, as they are familiarly known. Now the strange part of the tale is that the patient was a poor man, who had not even a howing acquaintance with such a *grand seigneur* as a Napoleon! The three coins must, therefore, have been blown out of some comrade's pocket into the wounded man's leg!

"S."

AMERICAN RED CROSS IN SERBIA.

SKOBLJE, SERBIA, July 10, 1915.

Mr. Editor: I suppose that an account of the conditions in Serbia would be of special interest to your readers, but I am in no position to treat the subject adequately, nor would it be proper for a member of the American Red Cross Commission to attempt this without the aid and approval of its Director, Mr. Strong. Therefore, I wish to have it clearly understood that what follows are personal impressions and views subject to correction.

The epidemic of typhus in Skoblje seems to have been at its height in January or February and to have diminished rapidly during the month of April, so that when we arrived here in May comparatively few new cases were entering the Lady Paget Hospital which had been reserved for fevers, and for typhus in particular. This hospital was staffed by British and supported by the British Serbian Relief Fund. The members of the staff kindly allowed several of us to join in the work, and to live at their hospital in order that we might begin to study typhus without delay, and had it not been for this hospitality, we should have lost much time in getting settled.

They told me that they had begun work in one of the Serbian hospitals which had been a school, and had later moved into their present quarters, the Cadet Barracks, situated most beautifully in the midst of rolling pastures in the valley of the Vada, a mile above the town. They had found terrible conditions in the stables where Austrian prisoners were quartered hard by, and several of their hospital-staff had contracted typhus by going into these buildings to remove the sick and the bodies of the dead. Lady Paget took the disease in the same way.

The mortality among these prisoners seems to have been frightful at first and was due, probably, in great measure to lack of hospital care, or indeed care of any sort. After the hospital got running well and had an adequate staff of nurses the number of cases of typhus which entered began to diminish, although patients were being sent from all the neighboring towns and villages, and finally began to come from far distant places.

We had not been many days at the hospital when the last large lot arrived. They had been collected and brought to Skoblje by a sanitary train, and some of them lived nearly as far away as Belgrade. Having been sorted by the Serbian doctors in the town, those destined for the Paget Hospital began to arrive by carriage-loads in the afternoon. There were carriages, carriages, and still more carriages until the ground around the wash-house was covered with emaciated, unkempt humanity. The "bohnitchers," or Austrian orderlies, got busy with the dippers, tied the clothes into bundles, and lead the tottering patients into the wash room where they were duly scrubbed. Meanwhile brandy was given, where they lay, to the weakest, and it seemed as if some would die before they could be cared for. Then, skinny figures, clad in night-shirts, began walking across the grass barefooted to the ward buildings, and stretchers also were seen, but there was no confusion and no excitement.

* A writer in the *Lancet* makes the proportion of killed to losses among officers work out as high as 43.61 per cent.

Eighty patients were taken into the hospital that afternoon with perfect ease. However, 120 had been expected and the beds were ready of course.

Half of the new patients went into my wards where I looked them over, prescribed hastily on general principles, and singled out the sicker patients for special attention. It was several days before all had been examined completely. If you think you can diagnose typhus by the faces, try it under such circumstances. I diagnosed it freely only to find later that several of my supposed typhus cases had relapsing fever.

In Serbia there are "three typhuses", typhus exanthematicus or "pegavi-typhus," typhus recurrens, and typhus abdominalis, and in the recent epidemic here there has been a considerable percentage of recurrens, as has so often been the case in other epidemics of typhus fever. I have seen very few cases of typhoid fever, but among the patients sent to the Paget Hospital as "typhus" there has been a certain proportion of tuberculosis in its various forms, some malaria, a little diphtheria, and, recently, a large number of typhus suspects have been admitted for a disease afterwards designated "influenza", or "dogs' disease", and which may have been popotasi fever.

At the present writing there is little typhus anywhere in Serbia so far as I can learn, and that which persists is confined to a few localities.

G. C. S.

A NAUTICAL REMEDY FOR HICCOUGH.

DARK HARBOR, ME., Aug. 26, 1915.

Mr. Editor: In "Ancient Remedies for Hiccough," JOURNAL of Aug. 26, I note the omission of a remedy which I have heard was at one time considered sovereign by sailors: to wit, to spit tobacco juice on the testicles of the sufferer.

Yours truly,

F. C. SHATTUCK.

BELGIAN PHYSICIANS' RELIEF FUND.

REPORT OF THE TREASURER OF THE COMMITTEE OF AMERICAN PHYSICIANS FOR THE AID OF THE BELGIAN PROFESSION FOR THE WEEK ENDING AUGUST 28, 1915.

CONTRIBUTIONS.

Warren County Medical Association, Vicksburg, Miss. \$10.00

Receipts for the week ending August 28, \$10.00
Previously reported receipts, 7804.84

Total receipts, \$7814.84
Previously reported disbursements:
1625 standard boxes of food @ \$2.20, \$3575.00
1274 standard boxes of food @ \$2.30, 2930.20
353 standard boxes of food @ \$2.28, 804.84

Total disbursements, \$7310.04

Balance \$ 504.80

F. F. SIMPSON, M.D., Treasurer,
7018 Jenkins Arcade Bldg.,
Pittsburg, Pa.

NOTICE.

Until further notice the voice clinic of the Boston Psychopathic Hospital will be open daily except Monday from 3 to 5 P.M., for charity cases of all the phases of speech defects.

WALTER B. SWIFT, M.D.

SOCIETY NOTICES.

AMERICAN SOCIAL HYGIENE ASSOCIATION.—The annual meeting of the The American Social Hygiene Association will be held in Boston, Massachusetts, October 8, 1915. In connection with it there will be public meetings in the afternoon and evening, the latter to be held jointly with the Massachusetts Society for Social Hygiene. Details of the program are not yet completed but will be announced soon.

JAMES H. FOSTER, Assistant Secretary.

NEW YORK AND NEW ENGLAND ASSOCIATION RAILWAY SURGEONS.—The twenty-fifth annual session of the New York and New England Association Railway Surgeons, celebrating the quarter century anniversary of the organization of the association, will be held at Hotel Astor, New York City, October 21, 1915, under the presidency of Dr. W. H. Marcy, of Buffalo, N. Y.

A very interesting and attractive program has been arranged. Railway surgeons, attorneys and officials, and all members of the medical profession are cordially invited to attend.

GEORGE CHAFFEE, M.D., Corresponding Secretary,
338 47th Street, Brooklyn, N. Y.

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.—The twenty-fifth annual meeting of the Association will be held at Atlantic City, September 14, 15 and 16, 1915, with headquarters at the Hotel Chalfonte.

All physicians interested in physical therapeutics are invited to attend.

J. WILLARD TRAVELL, M.D., Secretary.

APPOINTMENTS.

UNIVERSITY OF NEBRASKA.—Dr. Oscar Theodore Schultz, formerly assistant professor of pathology in Western Reserve University, has been appointed professor of pathology and bacteriology in the University of Nebraska.

UNIVERSITY OF PITTSBURGH.—Dr. John Jenkins Buchanan has been appointed emeritus professor of surgery and Dr. Robert Tabbutt Miller professor of surgery in charge of the department.

Dr. P. H. Roemer, director of the Institute of Hygiene at the University of Greifswald, has been appointed to succeed Professor Fraenken at the University of Halle.

RECENT DEATHS.

DR. THOMAS F. AIKEN, who died in Boston on Aug. 16, was born at Oswego, N. Y. He received the degree of M.D. from the University of Pennsylvania in 1894, and after practicing his profession for a time in Philadelphia removed and settled in Boston. He is survived by his widow.

DR. N. W. WILSON of Buffalo, N. Y., died on Aug. 30, of cardiac disease, in New York City. He was formerly a resident Rutherford, N. Y., and after having engaged for a time in journalistic work he studied medicine at the Buffalo Medical College. He was a practitioner in Buffalo at the time of the Pan-American Exposition in that city, and was the first physician summoned to attend President McKinley when the latter was assassinated there.

DR. MARTIN BERNARD RODDY, of Lynn, Mass., a Fellow of The Massachusetts Medical Society, and of the American Medical Association, died at the Lynn Hospital, Aug. 12, following an operation for appendicitis, aged 29 years. He was a graduate of the Baltimore Medical College in 1900.

SURGICAL EXPERIENCES IN FRANCE.

BY WILLIAM JASON MIXTER, M.D., BOSTON.

WHEN I arrived at Juilly last February, Hospital B. of the American Ambulance was in running order and filling up fast. It is more often spoken of both in America and in France as Mrs. Whitney's Hospital as it was furnished and is maintained entirely by Mrs. Harry Payne Whitney of New York. The hospital was located in one wing of an old Jesuit college dating from the 12th century, which the French Government had requisitioned. There were no modern conveniences of any kind when Dr. Edward Martin and those associated with him began their work, and the mere fact that when we arrived it was a fully equipped hospital, with large airy wards, operating room, x-ray plant, ample cuisine, laundry, modern plumbing, steam heat and electric lights, shows what these men had accomplished. Juilly is about 30 miles from Paris on the road to Soissons, and is one of the innumerable small villages scattered among the beet fields of that part of France. The trenches lie 35 miles further out, swinging gradually north and east, and passing about 12 miles from Compiègne, which was 40 miles from Juilly. This town to us was the most important place in our vicinity, as it contained the distributing point from which almost all of our patients came.

When a soldier is wounded in the French trenches he has a first aid dressing applied by the medical officer or orderly, and is carried back

as soon as is practicable to the dressing station. Here his dressing is re-enforced, if necessary, and a diagnosis tag tied to his clothing, unless this has been done in the trenches, and, unless moribund, he is sent at once to one of the first line hospitals, or if the wound is slight, and transportation is at hand, to the distributing point in the rear. Here he is again looked over and final disposition made of the case, either to some local hospital in the army zone, or by rail to Paris or some of the larger base hospitals in the south of France. Penetrating wounds of the head, chest or abdomen are usually kept near the front until better able to travel, but most fractures and a certain number of these more serious cases are sent back from the first line. Of course the disposition of a given case depends to a great extent on the severity of the fighting at the moment.

The Palace of Napoleon III at Compiègne has been taken as the centre of hospital activity in this vicinity, and there are many wards for medical cases. The main hallway is entirely devoted to the work of distribution of the sick and wounded, brought here from the dressing stations and hospitals of the first line in the French military ambulances. Three times a week our convoy, usually four ambulances and one staff car, for the chief of ambulances, the doctor and the interpreter, went to Compiègne to receive the cases assigned to us by the major in charge. Those long rides were most interesting at first, but after a time they become somewhat monotonous, although always a change from hospital routine. It seemed strange, indeed, to go spinning along over those wonderful roads and never

meet an automobile, save occasionally some military car or motor-cycle, tearing along at forty, fifty, or even sixty miles an hour. Nothing impresses one as much as the complete absence of motors and of men of military age. If you see one in citizen's clothes you always look twice to see what he is and why he is there.

One rarely sees soldiers, except a certain number ploughing or lounging about the villages. There are no great camps, as the men are all billeted on the villages or housed in barns, storehouses and the like, and this, I am told, is true all through France. Later I did see a few camps back of the English lines, but nothing to what I had expected. Along all the railroads and on every bridge were guards, usually older men of the reserves, clothed in blue coats, buttoned back and the red trousers which have been immortalized by Detaille in his battle pictures of the Franco-Prussian war. It always seems to me that these old men, who do nothing but guard duty from one month's end to the next, have about the most miserable existence possible for a soldier. They are always keenly on the job, however, and you know when you see one step out to the middle of the road ahead of you and raise his rifle horizontally above his head at arm's length, that it is time to stop and have passes examined, or give the *mot*. As this happens every few miles it is easy to see that the passless motor will not get far.

Naturally passes are not given out freely, and to get one it is necessary to go to the headquarters of the army in whose zone you wish to travel, state your business and then, perhaps, you will get the necessary document. Passes for ambulances on a fixed route or in a definite area are given out for two weeks and specify the military number of the car, name and number of the driver, and name or occupation of the passenger (doctor, litter bearer, etc.). No passes given by the headquarters of one army are good in the territory of any other. Travel of all sorts is discouraged, and passes issued by the civil or military authorities are required whenever one

leaves the town in which he holds his *permis de séjour*.

At Juilly a great number of our cases were bullet fractures and severe wounds, not involving the body cavities. The peritoneal wounds, etc., stayed further front, while the minor injuries went further to the rear. Naturally, however, we had a few of both the more severe and the lighter type of wounded. A short time before I left Juilly I had in my ward of 50 beds, 25 bullet fractures, 1 brain abscess, 2 penetrating wounds of the abdomen, 4 penetrating wounds of the chest, and 1 septic knee joint, as well as several flesh wounds, closed fractures and severe sprains. Most of the wounds were caused by shell or shrapnel, with about 15% from rifle balls and a few by hand grenades. I saw only one bayonet wound and no sabre cuts.

Shell fragments and shrapnel almost always become septic, usually from the presence of clothing carried in by the missile, and the removal of the dirty, sodden mass of wool is probably more important than that of the missile itself. We found that it was of the greatest importance to examine the clothing wherever possible, in order to find out just how much we had to search for. Every case was x-rayed at entrance and if it was deemed advisable the missile was often localized later under the fluoroscope or by triangulation with two plates taken at different angles. Taken altogether, it seems to me these cases were chiefly of interest, not from an operative point of view, but as a constantly changing problem in immobilization and sepsis, although the nerve injuries were only slightly less in importance. Nearly all the shell and shrapnel cases were septic, and a moderate number showed clinically the presence of gas bacillus. It seems to me that this infection as a rule was less virulent in France than the few cases it has been my lot to see here at home, free incision almost invariably giving good result.

It has been said, and I believe correctly, that the gas bacillus varies tremendously in virulence, and that if carefully sought for, can be found in 90% of all shell and shrapnel cases. Clinically the case of gas infection is unmistakable,—a dirty gray wound discharging rather thin brownish gray pus, mixed with bubbles of gas, skin around the wound showing a pinkish brown discoloration, later turning to purple or chocolate, often, but not always, with fine crepitus beneath. There is always a peculiar, unpleasant odor to the pus and moderate elevation of temperature. At the suggestion of Dr. Allan Hervey, who had put in a good deal of time in Switzerland, we exposed a considerable number of septic wounds of various sorts, including the gas infection, to graded doses of direct sunlight, beginning with 10 minutes a day, with very gratifying results, as I do not remember a single case that did not improve under this treatment.

The immobilization of these fractures, which are usually complicated with one or two discharging wounds, forms a difficult problem, and

Fig. 4.
Septic fracture of both bones of forearm.

we found that plaster, either in the form of a bivalve or else with large bows of plaster built over wire netting, was usually the best.

In a certain number of cases, particularly badly comminuted fractures of the femur, a Steinman pin is most useful and is less painful than any other form of traction dressing, while Dr. Joseph Blake's modification of the Thomas splint is also extremely valuable. We did no bone plating, as we did not deem it advisable to open new tissue and traumatize uninjured bone in the presence of severe sepsis, and it should always be remembered that to immobilize successfully in the presence of extreme comminution it is necessary to use a very long plate, thus opening up a very large area for new infection.

Our usual procedure in a fracture case was to put on traction and do nothing to the wound, not even remove the bullet, unless the patient developed sepsis, when the abscess was opened, and bullet, clothing and unattached bone cleaned out as far as possible without opening up any new area. Loose bone fragments attached by periosteum we always left *in situ*, as such fragments make a good trellis for the formation of the callus.

Fractures of the long bones by rifle bullets, although often very extensive, usually remained clean, and we found it was necessary simply to paint the wounds of entrance and exit with Tr. Iodi and treat them as closed fractures. Of course, in a certain number of cases where fragments of bone had been driven out through the skin it was necessary to remove some of the loose pieces. Retained rifle bullets were rare, and usually could be left without danger to the patient. If the bullet had "upset" and small fragments were lying beneath the skin, we made a practice of removing them, but as a rule these did not become infected. In some of the recent articles I have noticed that the writers advised leaving all retained fragments, both bullet, shrapnel and shell, unless they cause abscess formation. We usually removed large fragments

Fig. 5.
Comminuted fracture of elbow with gas bacillus infection.

of shell and shrapnel ball, which did not involve the body cavities on account of the great danger of sepsis, and I feel, as these operations are usually slight after the missile has been carefully localized, that such a procedure is justifiable. I do feel very strongly, however, that prolonged search with opening up of much uninfected tissue is far more dangerous than a retained ball.

Wounds of the knee joint are not uncommon, and are among the most trying which one has to treat. In the Spanish-American war, and in the Russo-Japanese war, the results in these cases were much better than in the earlier wars, owing to the use of small calibre bullets and antiseptic surgery, but in the fighting in France conditions have changed again, and owing to shrapnel and shell fragments, the old conditions are more nearly approached. This is true more or less in regard to all wounds, and it may be said that the war surgeon now has the problems of those old days. A septic knee joint is a terrible injury, and almost always leads to permanent disability or even death. We found that light traction helped greatly to alleviate the pain, particularly when the wounds were dressed, and I believe that suction drainage, which was suggested by Dr. Carrel is of benefit, although my experience is too limited to speak confidently. I remember very distinctly the suffering of one Moroccan whose patella had been shattered by a large shrapnel ball. I sutured his patella and removed the ball and hoped vainly for a clean result. Low lateral drainage finally resulted in a cure of the septic process and the patella held. When I left he could flex his knee about 15 degrees and had far better function than if the quadriceps had been lost.

As I have said before, the French policy is to keep the most severe type of cases near the front, and the fact that we had only three deaths at Juilly during the time I was there tends to show that the judgment of the French surgeons at the front, both as regards diagnosis and prognosis, was uniformly good.

Fig. 6.
Chateau Annel.

It was my good fortune after leaving Juilly to spend three weeks in a first line hospital, and during this period to get a little glimpse of the French soldier, and the life immediately behind the firing line. Mr. and Mrs. C. M. Depew have given their chateau, which lies only three miles back of the first line trenches, as a hospital under the auspices of the British Red Cross. Nothing has been omitted which can add to the comfort or well being of the wounded, and yet, as is proper in a first line hospital, expensive and unnecessary equipment has been reduced to a minimum. One wing has been given over to hospital purposes, and the family, doctors, etc., live in the rest of the house.

It seems very unreal to live a quiet, peaceful, country house existence, with the trenches so close that rifle and machine gun fire is distinctly audible, and where one can, by going to the end of the park, watch the French shells bursting on the German gun positions if the artillery is firing. To me, perhaps, the most interesting part of this experience was the more intimate relation into which I was thrown with things military and the French officers. There were few days when we did not see scouting aeroplanes under fire, either French or German, and we soon learned to recognize the German shrapnel bursts by the slight violet tinge to the white smoke. An aeroplane at two thousand yards elevation makes but a small mark, and though the gunners seldom bring one down, the continuous firing keeps the plane so high in the air that accurate observation is difficult in the extreme. I have seldom seen a more striking picture than one of the graceful German *Taube* silhouetted against a clear blue sky with around and behind it thirty or forty round fleecy puffs of smoke left by a bursting shrapnel.

The cases seen were not unlike those we had at Juilly, except for the larger percentage of severe cases, some of which were moribund when brought to the hospital. It gives a greater sense of reality to see these poor fellows brought in

Fig. 7.
Ward at Chateau Annel (originally the ball-room).

fresh from the trenches, than even 24 hours later, as they were at Juilly. In fact, all through my stay in France up to my arrival at Chateau Annel the one thing that impressed me was the fact that the war seemed so unreal. Even the presence of troops and guards everywhere along the railroads was not convincing and I never could entirely eliminate the feeling of army manoeuvres.

On my way home I was able to spend a day at Boulogne and so to compare the French and the English. Boulogne is now a city of hospitals, and everywhere you turn you see hurrying ambulances, men in khaki, and Red Cross flags. In the town itself are many hospitals (I think fifteen in all) including the Casino and all the largest hotels, while all through the surrounding country are others, some under canvas, while others are in hotels, factories, etc. The work in the English hospitals seemed to be of a very high grade and in most respects similar to the French. Two differences struck me, however, one that the seriously wounded were being sent back from the first line more rapidly than among the French, the other that there was more specialization, one man doing all cranial work, and so on.

It was impossible for me to go to La Panne to see Dr. Depage and his work, owing to lack of time. Dr. Depage and his wife, who met her death so tragically on the *Lusitania*, meant a great deal to us here in Boston, and my inability to see him was one of my bitterest disappointments.

In looking back on the past four months and endeavoring to summarize in my own mind the surgical impressions I received, I think they fall as follows:—

1. Gun shot wounds do best if let alone as much as possible, unless there is some direct indication for interference.

2. All war wounds except those caused by bullets which do not "upset" will almost certainly go septic.

3. Gun shot fractures, even if septic, show remarkable powers of repair.

4. Military surgery is so different from civil surgery that those of us who would expect to serve, were this country to find itself at war, should have some definite training to fit us for our duties.

Convalescents ready to be sent to the dépôt.

THE COMMON SHOULDER INJURIES.

By EDW. H. RISLEY, M.D., F.A.C.S., BOSTON.

Assistant Surgeon to Out-Patients, Massachusetts General Hospital.

[From the Out-Patient Clinic of the Massachusetts General Hospital.]

It seems advisable from time to time that certain regions of the body should have their pathology and the end results of treatment studied or reviewed in order that our knowledge of the subject be brought up to date and certain obscure lesions further studied and have attention directed to them.

For the past two years it has been the author's privilege to have seen practically all of the cases of shoulder injury or disability treated in all of the rooms of the out-patient department of the Massachusetts General Hospital. These cases have been seen either directly in the two surgical rooms or by courtesy or consultation in the nerve, orthopedic or other departments of the out-patient service. In all some 450 cases have been seen and treated.

A review of these cases is here presented with the especial desire to direct attention to the so-called trivial injuries to the bones of the shoulder joint and to emphasize the fact that often

seemingly trivial or slight bone injury may be productive of very painful incapacity of long duration.

The author also wishes to emphasize the importance of early diagnosis and the payment of due respect, as trouble-makers, to such lesions as are ordinarily regarded as of minor importance, particularly such as injuries to the acromion and the greater tuberosity of the humerus and lesions of the acromio-clavicular articulation, all of which have formerly received scant attention.

The majority of shoulder disabilities are, of course of traumatic origin. This paper will not deal with arthritis except of traumatic origin, nor with diseased conditions, such as tuberculosis, but only with disability due directly or indirectly to trauma.

One very noticeable fact in this review is the great rarity of injuries to the brachial plexus. I think it can safely be said that nerve involvement in shoulder injuries is noticeably rare. Brachial plexus injuries occur only after great violence and rather more often in connection with dislocation than with fracture about the shoulder joint.

The shoulder joint, with its ample protection by large muscles, the laxity of its capsule, not allowing of extreme tension by effusion into the joint, and because of the influence of the weight of the upper extremity in the usual hanging po-

sition, aided by gravity in preventing destructive pressure of joint surfaces against each other after injury, when muscles are in guarding spasm, renders this joint one which is capable of more speedy recovery from injury than most other (weight-bearing) joints of the body.

On the other hand, in shoulder injuries the extent of the bony lesion by no means determines the severity of the immediate symptoms or sequelae. Often no grave lesion is to be found, and yet severe disabling and extremely painful symptoms may persist for many weeks or months, or a seemingly trivial bony lesion may also prolong for many months total incapacity out of all proportion to the extent of the lesion.

In this paper I propose to discuss the common injuries to the shoulder joint, especially from the point of view of treatment and probable duration of disability; as these two points are the ones on which our minds are most liable to be in doubt.

Shoulder injuries are liable to be very puzzling to one inexperienced in their diagnosis. If, however, one examines the shoulder and makes his diagnosis strictly by rigid methods of exclusion he will soon be surprised at the ease with which he can accurately diagnose these seemingly puzzling conditions.

Shoulder injuries group themselves into extra-articular and intra-articular lesions. The extra-articular are often more annoying to treat, though of course of less seriousness than the intra-articular. We believe that the extra-articular lesions merit more attention than they have formerly received.

An analysis of our series shows the order of frequency to be about as follows. This varies considerably with the time of the year.

1. Simple contusion or sprain of shoulder without fracture or other complication.
2. Subacromial bursitis.
 - a. Occupational.
 - b. Traumatic.
 - c. Secondary to some other injury or infection.
3. Fracture, insertion fracture or contusion of the greater tuberosity of the humerus or acromion.
4. Dislocation of the joint.
5. Ruptured supraspinatus tendon with or without separation of the greater tuberosity.
6. Fracture of the upper end of the humerus.
7. Chronic arthritis of the acromio-clavicular joint.
8. Occupational neuroses or pain (so-called).
9. Arthritis of the shoulder joint.
 - a. Traumatic in origin.
 - b. Old infectious joints.
10. Injuries to the brachial plexus.

The most common injury is simple contusion from falls or other external violence. These may or may not be accompanied by bone bruise, i.e. periostitis.

This type of case generally recovers with rest of the part, limiments and massage, in from one to four weeks, provided there is no bone injury.

There is one type of injury which is particularly painful, troublesome to treat and recovers slowly. This is the severe bruising of the greater tuberosity of the humerus, but without fracture. This injury should not be confused with the so-called sprain fracture of Ross and Stewart (to be spoken of later) as there is no separation of bony fragments, but only severe contusion of bone, probably setting up a localized periostitis. The x-ray generally shows slight roughening of the tuberosity, (Fig. 1). This

FIG. 1.

Bruising and periostitis of greater tuberosity. Old injury showing considerable localized osteoporosis. A type of injury producing prolonged disability.

injury results in very stiff and painful shoulders for one to three months, and is little affected by external applications or aspirin. They are stubborn to treat, probably because they often develop a bursitis in about one to two weeks after injury, and this adds to the discomfort and limitation of motion.

This injury has its counterpart in a similar bruising of the tip of the acromion, which gives practically the same chain of symptoms, but is less often followed by bursitis, and is nearly as painful and resistant to treatment as injury to the tuberosity.

The treatment consists of rest of the part, strapping, gentle massage with daily baking and very gentle passive motion.

In the clinics of other large hospitals beside our own, fracture of the acromion has been found to be quite common. Ross and Stewart report about 89 cases in 360 odd fractures. Three grades of severity exist.

- a. Well marked fracture with separation.
- b. Separation at the epiphyseal line.

c. Sprain fracture, which is by far the most common.

Sprain or, as we prefer to designate it, insertion fracture, about which it seems pertinent to say a few words at this juncture, is very common also in injuries to the greater tuberosity and occurred in about 30 of our cases.

Sprain fracture was first described by Callender in 1870 as a lesion in which some ligament or tendon is torn, carrying with it a flake or shell of bone into which its fibres are inserted. This injury, as would be supposed, is practically always caused by indirect violence, and is evidenced clinically by sharply localized tenderness and a small localized area of swelling over the immediate site of the lesion, and disability only such as would be caused by the pain attendant on motion.

I prefer the term insertion fracture as being more accurately descriptive of the lesion than the term sprain fracture, which is in no way descriptive of the condition.

X-ray evidence has not yet made it quite clear whether there is at first simply a tearing of a small bit of periosteum away from the bone by the tendinous or ligamentous pull, and that this then begins to proliferate, giving the fairly dense, bony(?) shadow seen, or whether actually more than periosteum is torn away primarily. Certainly in those cases described as "chip off" the greater tuberosity or acromion, the latter holds true. A larger number of x-rays of fresh injuries, followed by further x-ray one to two weeks later will settle this point (Figs. 2 and 3).

This type of fracture can be accurately diagnosed only by the systematic and careful employment of x-ray in all sprains. The x-ray may, however, fail to locate the lesion if it should not happen to be taken in the proper plane.

Acute localized tenderness over a region of tendinous or ligamentous attachment is practically pathognomonic of insertion fracture, however, and this diagnosis can be made whether x-ray verifies it or not.

I am sure that the failure to make a diagnosis of insertion fracture, especially of the greater tuberosity and acromion, has led in large measure to the confusion that commonly exists in regard to lesions of the shoulder joint. Failure to diagnose this injury also leads to wrong treatment and prolongation of the period of incapacity. Treatment should be by absolute rest of the part and practically absolute fixation for one to two weeks, followed by gentle passive motion and massage for one to two weeks longer; three to four weeks should suffice to make the arm useful again.

Definite well marked fractures of the acromion are rarer than the other two types, and are more often accompanied by injuries to the outer end of the clavicle or luxation of the acromio-clavicular or coraco-acromial joints.

The traumatic condition of the tuberosity, which is even more painful and disabling, is well marked in fracture of this part, which is generally accompanied by some rupture of the supraspinatus tendon, or else the tendon, if not torn from its insertion in the tuberosity, pulls the fragment of tuberosity upward, producing noticeable inability to abduct the arm actively from the side and much pain on all motions. The picture without x-ray would, of course, be that of ruptured supraspinatus, but with more pain. Only in rare instances, however, is the separation great enough to warrant attempts to sew the displaced tuberosity down to the head of the humerus again. The two cases in this series operated on with this end in view have practically

FIG. 2.

Typical insertion fracture of greater tuberosity.
Marked osteoporosis.

FIG. 3.

Insertion fracture of greater tuberosity with accompanying bursitis.
Slight osteoporosis.

perfect results, but with no saving in time over the less radical procedure of putting the arm up in semi-abduction by means of a double internal angular splint, one arm of which rests against the side of the body. (Described by Penhallow and Osgood, *J. A. M. A.*, July 31, 1909, vol. xvi.), and with firm pressure over the tuberosity until fibrous or bony union takes place. These arms are generally useful again in from three to six weeks.

Subacromial or Subdeltoid Bursitis. The analysis of this type of cases in our series brings out two points in the etiology of this disease which we believe have not heretofore received much attention, and which are of utmost importance in the understanding of this lesion, its treatment and especially its prognosis. These facts are as follows:—

(a). Subacromial bursitis practically never develops as the result of a fall or strain producing injury to the bursa alone, but practically every case of bursitis, if examined carefully by x-ray, will show one of the following lesions as the cause of the bursitis: fracture, insertion fracture, periostitis or simple contusion of the greater tuberosity or acromion process, hypertrophic arthritis of the acromioclavicular articulation, luxation of the articulation, fracture of the clavicle or fracture of the head of the humerus. An analysis of 200 cases diagnosed as bursitis shows that in 30% of these cases no x-ray was taken, and therefore we believe a positive diagnosis was not made and cannot be made without x-ray in every case. Analysis of the remaining 70% who had x-rays shows the great prevalence of real lesions as the causative factor in producing bursitis. X-ray was negative in only 10 cases. In 25 cases a thickened bursa was shown. In 25 a roughening of the tuber-

osity such as is produced by direct trauma. In 6 cases there was the osteoporosis of trauma. (See Figs. 1, 2, 3.) In 7 some other injury of the greater tuberosity. In 6 actual fracture of tuberosity. In 10 separation of the acromio-clavicular articulation. In 9 fracture of the tip of the acromion. In 7 insertion fracture of the tip of this bone. In 8 arthritis of the acromio-clavicular articulation. (Fig. 6.) In one case apparent calcification of the supraspinatus tendon. In 12 cases calcified nodules in the bursa.

Thus we come to realize that subacromial bursitis is not a lesion of the bursa *per se* as a result of trauma to it, but is practically always secondary to some other neighboring bone or joint involvement.

(b). Nearly 60% of subacromial bursitides are of the occupational type, *i.e.* occurring in such trades as the tailor, cigar maker, telephone operator, shoe-machinery worker, cobbler, etc., or, in other words, those whose occupation requires them to make certain fixed and limited motions with one or both arms. This has been pointed out and explained by Codman in his excellent paper as follows: Certain regular but restricted motions of the arm, as when the cigar maker rolls cigars, produces in the subacromial bursa a constant limited area of friction in the base of the bursa, which, as it proceeds, gradually produces a tuft of inflammatory tissue on the floor of the bursa, and the infringement of this tuft of sensitive tissue on the acromion as the arm is raised or lowered produces the characteristic abduction pain found in these cases.

Several young girls, telephone operators, who use certain limited motions of the arms in "plugging" in their wires into the switch board, have been treated in our clinic for this occupational type of subacromial bursitis and have exhibited the typical picture of pain on motion (especially the occupational motion), referred pain up and down the arm, inability to get arm in a comfortable position at night and limitation of motion due to pain. In these cases there is no swelling, but a point of local tenderness can often be found over the bursa or at the deltoid insertion.

Three forms of treatment will cure the three grades of severity: (a) Rest from one to three weeks will cure the mild cases, but there is always danger of recurrence on resumption of the former occupation; (b) change of occupation when this is possible in more persistent cases not cured by rest; and (c) in stubborn cases and in those who are unable to change their occupation, excision of this inflammatory tuft is the only means of giving sure relief.

This can be done easily and quickly under novocain anesthesia. The bursa is easily exposed through the separated deltoid fibres, opened; the inflammatory tuft, which is practically always demonstrable, even at a distance, to those looking on, or adhesions, which are very common, excised and the wound closed. Mus-

Fig. 6.

Hypertrophic arthritis of acromio-clavicular articulation. A very common cause of obscure and prolonged shoulder disability.

cles which have been in guarding spasm are best rested after operation for three to four days by putting the arm up in abduction. This is readily done by bandaging the forearm to a wooden splint and fastening the splint over the patient's head to the bed post. As soon as the wound is solid, massage, passive and gentle active motions are started and the arm should be ready for use again in three weeks.

The area formerly occupied by the inflammatory tuft now becomes covered with normal scar tissue, which, as it hardens, forms a non-tender impinging surface, which is a better working surface than the older softer (?) bursa floor. The author has not had the opportunity to re-open any of these cases, but as they practically always get relief from operation, even if they return to their former occupation, I think the assumption is correct that this normal scar tissue is a better surface than the irritable bursa floor.

Acute traumatic subacromial bursitis with effusion into the bursa, causing intense pain, is not uncommon. These may also be of infectious origin as instanced by several writers and seven cases in our own series resulting directly from septic foci lower down in the arm or hand.

Cases of acute, infectious subacromial bursitis secondary to infections elsewhere in the body are not at all uncommon. In our series there were three cases following sepsis of mild degree in the fingers or hand, such as septic abrasions or splinters. One case followed a severe burn of the arm. Two cases have been found in patients after scarlet fever and one after an acute gonorrheal urethritis. (The bursa was not aspirated in this case and hence no culture was obtained from the infected area, but as no other fact would so well explain the case it seems fair to suspect strongly the gonococcus.)

The pain of bursal distention is so great that the arm is absolutely incapacitated and the spasm of surrounding muscles is great. Five such cases have been aspirated with a small needle with immediate relief of pain and improvement in motion.

If, after trauma, there is no excess of fluid, but acute pain, the use of the actual cautery, making point blisters over the surface of the shoulder, is of great benefit and generally gives immediate and permanent relief in acute cases, but has little lasting influence in chronic cases.

Injection of the chronically inflamed bursa with 70% alcohol has been tried on a small series of cases, but without giving any permanent relief.

The cases of subacromial bursitis secondary to injury of some neighboring structure are generally of the chronic or subacute type and more resistant to treatment. They may persist for several weeks or even months after fracture of the greater tuberosity or slight rupture of the supraspinatus tendon, and are best treated, after the primary injury is healed, by passive motion, baking and massage. Thus the whole disability may extend many weeks after the primary injury is cured.

Several cases of subacromial bursitis, developing rather suddenly after trauma or, in three cases where the patient, a nurse, was worn out physically from a succession of hard cases, showed by x-ray the dense shadows of calcareous deposits in the bursa. There was very acute tenderness over the bursa, but no signs of fluid, pain such as to require repeated doses of morphia and total inability to use the arm for from ten days to three weeks. Figs. 4 and 5 show very interestingly what may happen in such cases. Fig. 4 was taken at the height of the

Fig. 4.

Taken at onset of acute symptoms and showing marked calcareous deposit in subacromial bursa.

Fig. 5.

Same shoulder taken two years later showing complete absorption of deposit in bursa. Patient well.

acute symptoms in October, 1912. Fig. 5 was taken in April, 1915, and shows the total absorption of the calcareous deposits; the patient now being free from symptoms for the past two and one-half years. This x-ray is of great interest and importance in throwing light on the processes taking place in the bursitides.

Ruptured Supraspinatus Tendon. These cases are of great interest from the point of view both of diagnosis and results, both with and without operation.

In our out-patient clinic for the past five years there have been 32 cases diagnosed as ruptured supraspinatus tendon. These do not include cases operated on in the House. Of these 32, only 10 have been traced. All of the ten are now well and free from symptoms or disability. Three received out-patient treatment and were then recommended to the House, but were not admitted, and presumably had no treatment except rest and liniments at home. Three that were diagnosed as ruptured supraspinatus by other departments, were operated on by the author and were found to have only firm adhesions in the bursa. Those cases not traced I think we can assume are well or they would have come back for treatment.

From these facts it is evident that the absolute diagnosis of ruptured supraspinatus tendon is not easy to make and probably should be made in only a very few cases until after the subsidence of all other symptoms due to injury of surrounding structures. It seems fair to set a time limit of at least three months after injury before an absolute diagnosis can be made, the reason being that so many other injuries, such as severe strains or contusions to surrounding parts, give symptoms during that time and before their subsidence, identical with those of ruptured tendon. This is why Codman says he never operates on an acute case.

Adhesions in the subacromial bursa are often diagnosed as rupture of the supraspinatus tendon. These cases are operative, however, and therefore a mistake in diagnosis does the patient no harm. I think we can lay down the rule that all fresh cases diagnosed as ruptured supraspinatus and not improving under routine treatment after three months should be subjected to an exploration of the bursa and tendon.

Even cases of much longer standing are often relieved by operation for freeing of adhesions. This is well illustrated by the case of Mrs. M. H., 64 years old. P. H. Fell down stairs fourteen years ago and landed on right shoulder. Acute pain for three weeks. Has never been able to raise arm from side or get it up to head since, but has had little pain except on attempts at motion. Had been to many doctors without relief. P. E. A white haired, stout old lady. Marked atrophy of the right deltoid and spinati. External rotation very painful. Abduction from side possible only for a very few degrees and painful. X-ray shows distinct roughening over the greater tuberosity of the humerus. At op-

eration the bursa was found to contain several strong bands of fibrous tissue which markedly restricted motion. These were excised. One month from time of operation patient could move arm freely in all directions without pain, and in six weeks considered herself perfectly well. Operation November, 1912. Function is now normal.

Several cases of just this type have been operated on and afforded relief from long standing disability.

The symptoms are very similar to those of rupture of the tendon which has for its cardinal signs and symptoms:—

(a) History of trauma, generally a fall with attempt to save oneself, thus causing severe strain of the shoulder.

(b) Inability to abduct arm from side actively.

(c) Inability to hold arm at horizontal against pressure after it has been placed there by the examiner.

(d) Pain, especially at the deltoid insertion, and over the site of the tear in the tendon, on attempts at abduction.

(e) External and internal rotation practically normal.

These are the typical signs of rupture of the supraspinatus tendon. Adhesions alone in the bursa may cause the same chain, but are more liable to be accompanied by more pain on motion and some restriction of the rotary movements.

Recurrent Dislocation of the Shoulder. We have had under observation three cases of repeatedly recurring dislocation of the shoulder in epileptics who were under medical treatment, and while only one of these has lately consented to operation and the one case on which T. T. Thomas' anterior capsulorrhaphy was done has now a recurrence, we believe from the study of the anatomy of the shoulder joint, both in the cadaver and the living, and the pathology of the dislocation, that this operation is the one which should in a larger series of cases give satisfactory good results. (*Annals of Surgery*, 1913-1915).

Arthritis of the Acromioclavicular Joint. This is a condition very similar in symptomatology to that of bruising or fracture of some degree of the greater tuberosity, especially in its painfulness and resistance to treatment and the later development of a bursitis. It seems to be practically always of traumatic origin, and may be entirely a solitary condition and not associated with arthritis in the shoulder joint or elsewhere in the body. We have seen over 30 cases in which it was a purely non-articular lesion following trauma. (Fig. 6.)

Absolute rest of the part with strapping and Velpeau bandage to restrict the joint entirely, together with baking and gentle massage, without passive motion for from three to eight weeks, may be expected to give relief but not always a cure. Relapses are frequent and the condition is an unsatisfactory one to treat.

Occupational Neuroses. Occupational pain *per se* in the shoulder I do not think exists. As this paper deals only with lesions immediately connected with the shoulder joint the consideration of such conditions as brachial plexus neuralgia or neuralgia or neuritis of its branches is not entered into in this discussion.

The occupational pain described in this paper is that arising wholly from lesions involving the shoulder girdle and its component parts.

I believe, however, it is not uncommon in other regions, such as neck, forearm, finger, etc., but the anatomy of the shoulder joint and the *modus operandi* of the production of the lesions thereof preclude such a thing as occupative pain or neurosis here. Careful search of such alleged cases will always reveal some such condition as bursitis, arthritis, periostitis or one of the several degrees of fracture of the acromion or greater tuberosity.

Its treatment is that of the underlying lesion. For instance, the tailor who complains of pain in his shoulder and down his arm, does not have this pain only because he is using one arm too continuously, but because he has a subacromial bursitis caused by his certain, regular, restricted motions.

So also the man who sustained a slight fall six months or a year ago, which he had entirely forgotten, and who, after perhaps several weeks of rather harder work than usual begins to have troublesome pain in his arm or shoulder, does not have this pain simply because he has been working harder, but because (as x-ray will often show) he has an arthritis of the acromio-clavicular joint due to the old trauma, or some such underlying lesion.

Cases of this kind, so often diagnosed as occupational neurosis, either because the examiner is not skillful in making the diagnosis of shoulder lesions by exclusion or has failed to have an x-ray, are very common. Only rarely do we find patients whose occupation requires strained efforts on the part of certain muscles. These people, however, may have pain at muscle insertions, and often careful x-ray search will reveal typical insertion fracture at the point of muscle attachment.

Arthritis. I can refer here only to the traumatic type. Very few of these cases are seen in the regular surgical clinic as most of them are seen in and treated by the orthopedic department of a large hospital. The subject is a broad one. There have been found, however, in our clinic certain cases which complain of stiff, painful shoulders with marked actual limitation of motion, both active and passive, occurring several months after a more or less severe injury, in which x-ray shows the typical picture of arthritis with bony overgrowth and osteoporosis. These cases have much pain and are resistant to treatment and are sure to result in incapacity of long duration extending over months and even years.

Our experience with forced manipulation, under an anesthetic, in these cases has not given a large percentage of good results, unless the process has entirely quieted down and has remained quiescent for a considerable time, for like the infectious type, they may be stirred into activity by too early motion. After varying lengths of time, from perhaps four to eight months, of relative rest, the joint may be safely manipulated and relief afforded. Earlier cases are sure to be stirred up into renewed activity and have to go through a second long period of fixation and rest before they become useful again.

For patients who can do so the resort to balking, gentle passive motion and massage affords relief for this type of case in a shorter period than any other form of treatment, as a general rule. This must be persisted in, however, for many weeks continuously in order to be of any value at all. Such systematic and measured treatment and motion as can be obtained in a Zander department, such as the Massachusetts General Hospital affords, is of inestimable value in treating these cases. The economic saving in length of disability afforded by the careful methods of Dr. Hermann Bucholz and his assistants in this department is of incalculable value. The author would like to take this opportunity of thanking Dr. Bucholz for his interest and help in consulting over these often troublesome shoulder disabilities.

Rupture of the Brachial Plexus. As was first stated in the first part of this paper, these injuries are of extreme rarity as compared with other injuries to the shoulder joint. The records of the Massachusetts General Hospital show only 30 cases treated in the past fifteen years.

It is believed that operative exploration of the plexus should practically always be employed, provided thorough and systematic treatment by massage and electricity has failed to show improvement after at least three months' trial. Oftentimes early operation will allow of proper suture of torn nerve roots before retraction has taken place, while delay will make the operation exceedingly different or absolutely impossible because of the denseness of scar tissue formation.

In the small series of cases treated here the results from exploration and either freeing of dense scar tissue or suture of ruptured roots have at times been brilliant and at other times absolute failures. Early exposure gives the best results. In this series there were 15 cases of complete rupture, 7 of which were untreated because of the extent of the injury or refusal on the part of the patient. In 4, the exploration only was done, further operative procedure being impossible because of the extent of rupture or of scar tissue. Four cases had suture of the plexus or individual cords. One had an anastomosis of the musculo-spiral and ulnar nerves, with partial relief. The prognosis is not good in most cases. We believe, however, that with earlier operation more cases will be benefited.

SUMMARY.

In closing we wish to lay emphasis on the following points:—

1. Diagnosis in shoulder injuries is not made by clear cut signs and symptoms, but only in a careful process of exclusion and x-ray examination in every case.

2. X-ray is of the utmost importance in every case as it often reveals the underlying cause of a persistent bursitis to be some of the frequent lesions of the greater tuberosity or acromion, which are very often overlooked unless especial search is made for them.

3. About 60% of subacromial bursitis cases are of the occupational type. The remaining 40% have as an underlying cause in the great majority of cases, some lesion of the greater tuberosity or acromion.

4. The diagnosis of ruptured supraspinatus tendon should not be made until at least three months of non-improvement have elapsed.

5. Cases of long standing bursitis with adhesions give a picture identical with that of ruptured supraspinatus tendon and give extremely satisfactory results from operation.

6. Calcareous deposits in the subacromial bursa may be spontaneously absorbed.

7. The term insertion fracture should be substituted for the non-descriptive term of sprain fracture.

8. Occupational neurosis *per se* does not exist in the shoulder joint.

9. Injuries to the brachial plexus are rare. The percentage of patients benefited will be greatly increased by early exploratory operation.

10. Slight injuries to the greater tuberosity and acromion process and arthritis of the acromio-clavicular joint are of far greater importance than generally supposed in prolonging disability after shoulder injuries.

11. The author wishes to lay especial emphasis on the importance of these seemingly trivial injuries to the shoulder joint as factors to be considered in diagnosis, prognosis and treatment.

it into a needle. This method meets the requirements of any case, whereas when using needles, cases arise where no vein can be seen. The use of sodium citrate was discussed at the time of introducing this tube, but it is absolutely unnecessary and therefore is not advisable. I have by this method transfused more than 70 cases, including a great many new born babies, and a failure to transfuse the patient has not been encountered.

Technic. The skin over veins just below the elbow in the arm of the donor and recipient is injected with novocaine. The veins are exposed cleanly through incisions not over $1\frac{1}{2}$ inches long. Two ligatures are placed under the veins, but not tied, one above and one below. A tourniquet is now placed on the donor's arm tight enough to give venous congestion and still allow arterial blood to flow in. This vein is now tied off proximally, and the distal ligature is left to be used as a clamp by merely raising it a little after the vein is opened. If there is no assistant present, the weight of a hemostat hanging from the ligature will control the vein.

The donor's vein is now transfixed by a cataract knife and a slit made. The cannula of a tube is inserted into the vein of the donor and held upright until filled by venous pressure. (Fig. 1.) This usually takes not over two or

FIG. 1.

three minutes for a 250 c.c. tube. If not filling well it probably means that the tourniquet is too tight, or that the end of the cannula is against a valve or the side of the vein. The donor is instructed to shut and open his hand tightly and slowly. This, perhaps, hastens the inflow.

While the tube is filling, the vein of the recipient (without the aid of a tourniquet) is tied off distally, the proximal ligature being used as a clamp, and the vein opened. By this time the tube is full and the tourniquet having been loosened, is withdrawn and held on its side with the side-tube uppermost to prevent the blood from running out. (Thumb over end of side-tube, finger over cork, Fig. 2.) The cannula is now inserted into the vein of the recipient and held in an upright position. (Thumb under side-

TECHNIC OF TRANSFUSION BY MEANS OF GLASS TUBES.*

BY A. R. KIMPTON, M.D., BOSTON,
AND
J. HOWARD BROWN, M.S., BOSTON.

The following method of transfusion is one of the many indirect methods and is now very broadly used. Recently descriptions of glass tubes closely resembling this one, but leaving out essential features, have been published. The method requires an incision, but can be combined with needle operations if desired, by merely cutting the cannula end of the tube flush and fitting

* From the *Harvard Medical Bulletin*, page 34, May, 1915.

bar at junction with cylinder, finger over cork. (Fig. 2.) (Fig. 4.) Be sure the vein of the re-

FIG. 2.

cipient is bleeding before inserting cannula.) The little angular forceps is a great aid in introducing the cannula into the vein, especially when the lumen is small. (Fig. 3.) An actual can-

FIG. 3.

tery bulb is attached to the side-bar, and by a little pressure the tube is emptied. (Fig. 4.)

FIG. 4.

The cannula is withdrawn while there is still a little blood left in it. More tubes may be filled and emptied if desired, using the same veins. Pointing the cannula toward the hand of the donor is better than toward the heart, though both ways may be used. The veins are usually tied and cut, but if desired the slit may be sutured. If arterial blood is to be preferred the radial artery of the donor may be used, as was originally done.

Another use for the tube is in bleeding a patient. For this purpose the tube is used as in the donor's arm and when full the cork end is depressed, the blood emptied and the tube again

raised, without removing the cannula from the vein. The tube may in this way be filled and emptied a number of times and without removal from the vein.

As to the vein best to use in the recipient: if the patient is very thin I am in the habit of using the internal saphenous vein, in fact it is my preference under most conditions. At the same time, the vein in the arm is perfectly suitable. Using any means of suction in filling the tube seems to be of no advantage as the tubes fill readily. Furthermore, the walls of the vein can easily be collapsed by a little too much suction. The pump is boiled and therefore the operator can handle it himself.

Paraffining the Tubes. The tube is wrapped in a towel and sheet wadding, sterilized in an autoclave, and the paraffin mixture is sterilized either by boiling in a water bath or in the autoclave. (Vincent's mixture, stearin, paraffin, and vaseline in the proportions of 1-2-2. 54 degree paraffin may be used as well.) Personally I always keep my tubes paraffined ready for use, and they are paraffined by a nurse. Having scrubbed up, someone lays open a sterile package, the paraffin is kept melted in a water bath, and the tube is equally and moderately heated over one or two alcohol flames. (Not too hot. I find a Bunsen burner too hot.) Then remove the cork and pour in a lot of the melted mixture, the more the easier to do (50-60 c.c. for a large tube.) Allow this melted mixture to run around inside the tube and over the surface of the cork, and a little to run out of the cannula. Then turn it upside down in such a way as to allow all the paraffin to run back into the tube and out the side-bar into the paraffin jar. With a teaspoon seal the junction of the cork and glass on the outside with paraffin. It is much better and easier to let the paraffin run back out of the cannula than to suck out the last drop with a piece of gauze, as first described. Take an alcohol sponge and rub over the tube that it may cool more quickly.

The tube is now replaced in the sterile package and pinned up ready for use. I always clean my own tubes, and there is no necessity for breaking them. However, should a cannula happen to be broken, it can be repaired.

Cleansing. If you have very hot running water the tube can be cleansed with the greatest ease. If you allow the blood to stand in the tubes, or the tubes are left in water, it will be difficult. When through with the transfusion, have steaming hot water from the tap run through the tubes. I do this before removing my gloves. First, allow the water to run through the cannula end so that the paraffin melts and carries the blood back with it into the tube. The cork being removed, the water is allowed to run out. The rest of the paraffin is cleaned out in the same manner. Then, pouring in some tincture of green soap with the hot water, shaking the tube, and afterward rinsing until the tube is

clean, is all that is necessary. The tube is then pinned up ready to be re-sterilized.

[P. S. One criticism of this method has been that the veins are tied off, and another, that it is necessary to make incisions.

In regard to the first criticism, I no longer tie off the veins, but make a small slit in the vein, and at the end of the operation I tie this slit off laterally with fine silk. With rare exceptions this can be done, leaving this vein intact.

In regard to the second criticism, cases certainly arise that are so badly bled out that it is practically impossible to insert a needle into a vein, and, therefore, an incision is necessary even with the needle methods.

Again, we all know that at times much difficulty arises in inserting needles even into well-distended veins. A small incision makes the method certain and accurate. Recently I have had the opportunity to transfuse a patient by bringing out all these points, the patient having previously been transfused in another city by syringe methods. In this case it had been necessary, by the syringe method, to cut down on the vein of the recipient, and there also had been much difficulty encountered with the vein of the donor, so that the operation by the needle method lasted about two hours, while the operation by the above method, giving practically the same amount of blood, lasted fourteen minutes. In cases such as this, shortening of the operation is a decided advantage].

THE USE OF THE SCHICK TEST IN A CHILDREN'S INSTITUTION.

BY HARRY LINENTHAL, M.D., BOSTON.

Physician to Out-Patients, Massachusetts General Hospital;

AND

SOLOMON H. RUBIN, M.D., BOSTON.

Physician to Out-Patients, Norfolk State Hospital.

DURING the months of October and November, owing to the prevalence of diphtheria in Boston, it was suggested that all the children in the Home for Jewish Children in Dorchester, one hundred and twenty-six in number at that time, be immunized by prophylactic doses of antitoxin. The occurrence of a case of communicable disease in this Home is a very serious matter, inasmuch as all the children are excluded from school for a period corresponding to the incubation period of the disease, and the children are thus deprived of their schooling for consid-

erable lengths of time, even if the child afflicted with the disease is immediately removed from the Home. While the immunity conferred by antitoxin is not lasting, it was thought that by thus immunizing the children and tiding over the period of the prevalence of the disease, the chances of the occurrence of cases of diphtheria in the Home would be minimized.

Recent researches, particularly those of Schick of Vienna and Park of New York, had shown that large percentages of children, varying from 50 to 80%, possess sufficient antitoxin in their blood serum to make them immune to diphtheria. The administration of antitoxin to all the inmates of the Home would therefore have meant that many children who were naturally immune would have been subjected to this needless procedure. To separate the immunes from those susceptible to diphtheria we utilized the test devised by Schick for that purpose.

The Schick test consists of injecting under the superficial layer of the skin, usually on the flexor surface of the upper arm, one-fiftieth of the dose of diphtheria toxin required to kill a guinea-pig of two hundred and fifty grams. Schick originally used 0.1 c.c. of normal salt solution for the dilution of the toxin. We followed the modification of Park of New York who used 0.2 c.c. of normal salt solution as a diluent. A fine short pointed platinum needle was used for the injection. A raised bleb appears at the point of the injection, which disappears in a few minutes. Within twenty-four to forty-eight hours after injection a fairly well circumscribed area, bright red, with a pale, slightly indurated center, appears at the site of the injection in individuals susceptible to diphtheria. This reddened area blanches on pressure and on stretching of the skin. It is, therefore, important in examining for the reaction, to flex the arm, otherwise the stretching of the skin of the extended arm may cause a well-marked reaction to disappear. We noted in a great many of the cases, on stretching the skin and blanching the reaction, a faint circle of pigmentation around the point of inoculation well within the circumscribed area of redness. The degree of the reaction varies inversely to the antitoxin contents of the blood, and we had all grades of reaction, from very mild to well marked. The variation, consists chiefly in the size of the area of redness and in the intensity of the coloration. This reaction lasts for several days, and gradually fades, leaves a pigmented, slightly scaling area which may persist for two weeks or more. The reaction is not accompanied by any constitutional symptoms or local discomfort. All the children who gave positive reactions, whether strong or mild, were given immunizing doses of 750 units of antitoxin, and their susceptibility tested again at various intervals, by the further administration of toxin. We found that after four weeks 50% of those to whom antitoxin had been administered, gave a positive reaction, indicating the disappearance of the immunity conferred by the

antitoxin. In several cases the immunity persisted after eight weeks, and in six of the children immunity still persists, five months after the administration of the antitoxin.

Previous to starting the tests, cultures were taken from the noses and throats of all the children. Three carriers were discovered; two of these gave negative Schick reactions. One of the carriers gave a positive reaction; on testing out the organism, however, it was found to be avirulent.

TABLE SHOWING RESULTS OF THE SCHICK TEST.

Age.	No. of Cases.	Number Positive.	Number Negative.
5	1	1	0
6	6	3	3
7	10	2	8
8	20	9	11
9	9	2	7
10	20	4	16
11	17	6	11
12	13	2	11
13	12	5	7
14	11	2	9
15	4	0	4
16	3	0	3

Of the total one hundred and twenty-six children only thirty-six, or approximately 29%, gave positive reactions. Ninety, or 71%, showed themselves by the negative tests to be immune to diphtheria. Instead of administering antitoxin to one hundred and twenty-six children we had to give it only to thirty-six, and thus saved for the state considerable antitoxin and avoided the subjecting of the immune children to the annoyance and the danger, however remote, of the unpleasant effects that are apt to follow the administration of horse serum.

Five months after our first test, we injected again diphtheria toxin to all the children and we found our results strikingly uniform with our first tests, with the following exceptions:—

Six of the children who on the first examination gave positive reactions, and who received immunizing doses of antitoxin, gave, five months later, negative reactions, showing the persistence of the antitoxin immunity. Of these, two were eight years old, one nine years old, two ten years old, and one eleven years old. One child fourteen years old, who gave a negative reaction on our first examination, gave a positive reaction on the second examination. With the exception of this last case all the children who gave negative reactions the first time, gave negative reactions on the second test five months later.

We are unable to explain the one case which showed itself immune on our first test and was found susceptible in a subsequent examination five months later.

From the general uniformity of the reaction at an interval of five months this test is of practical value in all the children's institutions, even in the absence of diphtheria. A record can be kept as to which of the children are immune

and which are susceptible. Antitoxin could then be promptly administered to the non-immunes should a case of diphtheria occur in the institution.

A fact worthy of note is the persistence of immunity in six children for as long a period as five months after the administration of antitoxin. We expect to keep these children under observation and test their immunity from time to time.

SUMMARY.

1. Of one hundred and twenty-six children, ranging in age from 5-16 years, thirty-six were found susceptible to diphtheria and ninety were found immune.

2. Antitoxin of 750 units administered to the non-immune produced an immunity which did not last over four weeks in 50%, in several as long as eight weeks, and in six children the immunity conferred by the antitoxin persisted after five months.

3. With the exception of the six children with the persistent antitoxin immunity and one child who gave negative reaction the first time and a positive the second time, the results of two tests, five months apart, were uniform.

4. The test is of great value in determining susceptibility to the disease and thus serves as a guide to determine in the event of exposure to diphtheria, who should and who should not receive prophylactic doses of antitoxin. Persons naturally immune will thus be saved the annoyance and the possible disagreeable results apt to follow the injection of horse serum.

In carrying out this work we are indebted to the State Department of Health for furnishing us the diphtheria toxin and to the Boston Health Department, who examined all our cultures and tested the diphtheria organisms for virulence.

Clinical Department.

A CASE OF ANTERIOR POLIOMYELITIS WITH MULTIPLE PARALYSES, INCLUDING THE HITHERTO UNRECORDED INVOLVEMENT OF THE LEFT DIAPHRAGM.*

By PHILIP H. SYLVESTER, A.B., M.D., NEWTON, MASS.,

Junior Assistant Visiting Physician at the Children's Hospital, Boston; Instructor in Pediatrics at Harvard University.

[From the Medical Service of the Children's Hospital.]

It is not often, in a hospital like the Children's, that a patient may go through various services and departments for a period of several months with a mistaken or incomplete diagnosis.

* Received for publication on May 31, 1915.

This case is unique in being the only one of its kind on record, despite a comprehensive search of the literature, a case presenting rare difficulties of diagnosis owing to an unusual combination of signs and conditions, which obscured the complete picture through several services at our hospital, and cleared up finally, when obscuring conditions had ceased, making the diagnosis obvious.

Following is the case:—

J. B. Male, aged 4. Entered the orthopedic outpatient department of the Children's Hospital March 4, 1914, with the following history:—

Family History. Parents well, 5 brothers and 3 sisters well, no deaths, miscarriages or contagious diseases, no exposure to tuberculosis.

Past History. Full term. Normal delivery. Breast fed one year, measles at 4.

Present Illness. In November, 1913, had what was called "gastritis" following which both legs became useless. Has improved slowly but steadily since. Lately has seemed feverish.

Physical Examination. Physical examination shows flabby, pale child, temperature 100. Left lower lung has an area of dullness, bronchial breathing and bronchial voice sounds; respiration 36. Otherwise negative except for legs. Legs both thin, flabby, atrophied. Left: fair power in thigh, slight in quadriceps. Foot: long extensors and peroneals have some power, tendo Achillis markedly contracted. Foot in equinovarus. Right: only slight power in flexors of thigh, none in adductors, little in abductors, none in quadriceps. Foot held in stiff equinus, from tendo Achillis contraction. Hips in place, no flexor deformities.

Diagnosis. Old infantile paralysis of both legs, question of pneumonia. Referred to House Medical. Entered the medical service of the late Dr. Kotch, where the following additional physical findings were noted. Lungs, left back, from apex to mid-scapula, dull with bronchial breathing; from angle of scapula to base, dull with diminished bronchial breathing and medium moist râles. Liver $1\frac{1}{2}$ cm. below costal border. Right knee jerk present, Kernig present on both sides, no Babinski or clonus. White count 16,000; hgb. 75.

Diagnosis. Pneumonia, question of fluid, old infantile paralysis.

March 6. Aspiration left chest, no fluid obtained.

March 7. Comfortable, hungry, signs same, discharged home (in country).

Diagnosis. Unresolved pneumonia.

April 11, 1914. Returned to the hospital with the following story: Was pretty well after discharge, but has had more cough in the day-time than before, no whoop or croup; has had no fever, but much coryza. Physical examination showed 20 teeth, tonsils very much enlarged, few small glands of the neck. Chest symmetrical in shape and expansion, no bulging, heart 1.5 by 7 cm. Lungs resonant throughout; coarse, moist râles throughout. D'Espine's sign to the 5th thoracic vertebra. Abdomen soft, tympanitic, liver 2 cm. down, spleen not felt. Abdominal wall very lax, extremities as at previous note, except that tendo Achillis contractions were more pronounced, reflexes: P. = and R. to L. and D. Right knee jerk present, left absent; no Kernig or Babinski, no clonus. White count 16,300. Von Pirquet negative.

April 12. Left base dull with distant breathing, many râles, breath sounds diminished.

April 13. Left chest a little more dull than right. Marked difference in respiration, which is barely heard on the left, much more air entering right than left. Heart $3\frac{1}{2}$ cm. to right. Abdomen very much distended.

Diagnosis. Probable pleurisy with effusion in the past with present adhesions, fibrosis(?). On the same day the case was used for teaching, and the following diagnoses were considered:—

(1) Blocked bronchus.

(2) Pneumothorax.

(3) Thickened pleura.

(4) (and most probable) Bronchiectasis and emphysema.

On orthopedic consultation, paralysis of left intercostals was considered. Sputum examined, negative for T. B.

April 15. Air enters both sides alike; percussion on left side, modified tympany.

April 23. Note on lungs. Frémittus increased at angle of scapula to left axilla. Tympany marked from left axilla to base behind and to ant. ax. line. Frémittus here slightly less. Just inside spine of scapula breath sounds are broncho-vesicular; below, breath sounds are clear but very faint.

April 27. Lung note. Left, normal resonance above, increasing to tympany at about angle of scapula, strikingly similar and continuous with abdominal tympany; breath sounds clear but very much diminished over tympanic area; lower border of lung not made out. X-rays M 1468 and M 1469 show hollow viscera, containing much gas, no bismuth, behind heart shadow and into left axilla to third space. Diaphragmatic shadow not made out. (Photo "A.")

April 29. Fluoroscopic report, Dr. Holmes. Fluoroscopy shows high, rigid diaphragm on left at level of 4th rib in front; above, lung is clear. Heart displaced to right; below diaphragm is a large gas bub-

ble, apparently in transverse colon. The amount of gas is unusual. Stomach is empty.

Diagnosis. Paralysis of left diaphragm and relaxation of the bowel.

The difficulties attending the complete diagnosis (as far as the diaphragm is concerned) in this case were obviously due to the changing conditions, whose physical characteristics were such as to mask any symptoms or signs referable to the diaphragm. It is reasonable to suppose that the following conditions occurred in the order named:—

First. Paralysis of diaphragm was present from the beginning and concomitant with the other paralyses noted.

Second. A broncho- or lobar pneumonia occurred in which: (a) the lung expanded and pushed the diaphragm down, (b) dullness resulting therefrom masked any signs referable to the diaphragm.

Third. Delayed resolution over a long period still masked the diaphragm.

Fourth. Complete resolution allowed the diaphragm to be pushed up by the gas in the intestines, thus revealing the true condition.

In November, 1914, the child reentered the orthopedic service for tendon transplantation, when another physical examination and another x-ray showed conditions practically as on April 27. (Photo "B.")

April 9, 1915. Has been pretty well since last visit, has gained in weight and had only one cold last winter. Has no pain in legs but cannot use them. Abdomen usually protuberant, but pretty flat

away respiration. Litten's sign doubtful, very much less air enters left than right lung.

Muscular effort of shoulder girdle and intercostals is apparently the largest factor in respiration on the left. There is now a distinct groove along the 7th, 8th, and 9th ribs in front, producing a shallow, wide depression. Heart $3\frac{1}{2}$ cm. to right of mid-sternum. Left border not made out, owing to tympany. Abdomen slightly distended, very lax. Left side wholly paralyzed, right, no reflex in middle segment of rectus. Distinct bulge to left when sitting. Liver extends to costal border, (X-ray "C," and photograph "D").

FIG. D.

some of the time. Lungs: right, no abnormalities; left: base, tympany to third space in front with absent respiration; base in back from mid-axillary line, slightly dull to the 8th rib with diminished far-

Final Diagnosis. Anterior poliomyelitis resulting in multiple paralyses, including the hitherto unrecorded involvement of the left diaphragm.

AURICULAR FIBRILLATION AND COMPLETE HEART-BLOCK.

BY PAUL DUDLEY WHITE, M.D., BOSTON.

[From the Massachusetts General Hospital, Boston.]

The coexistence of complete heart-block and fibrillation of the auricles is uncommon. In 1913, Gallavardin and Dufourt recorded a case and cited thirteen other cases in the literature. The present report is made of a patient with auricular fibrillation in whom, during the administration of digitalis, there was a decrease in the degree of heart-block from complete to partial, accompanied by a change in the character of the ventricular complexes of the electrocardiogram and coincident with marked improvement in the patient's condition. The *R* deflection became more acute and of greater amplitude and the *T* deflection flattened.

CASE REPORT. E. H. B., 54 years of age. Family and past history unimportant except for an attack of "rheumatism" in 1904. Lues denied. Little tobacco; very little alcohol.

Cardiac symptoms began in 1908 with palpitation off and on. Dyspnea on exertion during the past year. Left sided hemiplegia April 30, 1912. At this time his pulse was slow, but there is no record of its rate or rhythm. The hemiplegia did not clear up for months, but at present (April, 1915) there is no sign of it. In April, 1914, an irregular pulse of 100 was found and digitalis was given. After three weeks, during which the tincture was administered in the dosage of 15 to 30 drops daily, a pulse rate of 28 was found and the digitalis was discontinued. On Oct. 21, 1914, because of distress on exertion, the patient consulted Dr. Putnam, who discovered an irregular pulse of 44, six months since the last digitalis had been taken. From this time until the middle of January digipuratum was given in the dosage of gram 0.1 to 0.2 daily. On the 14th of November the pulse was 28 and regular; on the 20th it was 26, and on this date the blood pressure was 135 mm. mercury systolic and 75 mm. diastolic. On November 25 an electrocardiogram (Fig. 2) and a polygram (Fig. 1) showed a complete heart-block with a ventricular rate of 27 and auricular fibrillation. At this time

the patient felt very badly and was dyspneic and weak. Rest in bed and continuation of the digitalis resulted in pronounced improvement in the general condition coincident with a gradual rise in pulse rate. On Jan. 6, 1915, another electrocardiogram (Fig. 3) was taken; this showed an irregular ventricular rate of 47 per minute, with persistence of the auricular fibrillation. In the electrocardiogram the change in the character of the ventricular complexes is clear. On April 10, 1915, the heart rate was regular at 35, and on April 27, two months since any digitalis had been taken, an electrocardiogram showed a regular ventricular action at 37 with auricular fibrillation. On this latest date the patient felt well and was able to work in his garden. Atropin gr. 1-50th injected subcutaneously produced no increase in rate while the pulse was regular at a rate of 43 on May 24, 1915. Dryness of the mouth was marked one-half to one hour after the atropin. Exercise also failed to change the rate.

Physical examination April 10, 1915, showed a large heart with apex impulse felt in the sixth space and with a loud rough systolic murmur heard at the apex. No thrill. No increase in supra-cardiac dullness. No edema. Pupils reacted normally. Knee jerks present and equal. Grips equal. Wassermann test negative.

SUMMARY.

In a patient showing heart-block and auricular fibrillation the heart rate rose from 27 with complete block, to 47 with partial block during the administration of digitalis and coincident with marked clinical improvement. The ventricular complexes of the electrocardiogram changed in character simultaneously with the decrease in the degree of block, the change in the *R* suggesting a more normal conduction in the ventricle.

The spontaneous return to a complete block has been accompanied by a continuation of the patient's good health.

The block is not vagal in origin, atropin having no influence on it.

Drs. W. H. Smith and Ralph Putnam very kindly made possible the report of this case.

New Instruments.

SUCTION AND IRRIGATION APPARATUS FOR THE DIAGNOSIS AND TREAT- MENT OF THE ANTRUM OF HIGMORE.

By JOSEPH PRENN, M.D., BOSTON.

THE apparatus as shown in the cut is manipulated in the following manner:—

After the trocar, size 8 or 10 French, is introduced in the usual manner under the inferior turbinate and the inner wall of the antrum punctured, the stopcock nearer the rubber tubing, the free end of which is immersed in the solution, is opened and

the fluid is drawn into the syringe. This stopcock is closed and the middle one opened. The fluid is forced into the antrum through the trocar and then withdrawn together with the contents back into the glass syringe by suction. The middle stopcock is then closed and the last one opened, which allows the syringe to empty itself through the other rubber tube. The same process is repeated if necessary.

When more irrigations are required on subsequent visits, the trocar can be replaced by an ordinary eustachian catheter attached to the rest of this apparatus.

The patient has proven to be a valuable assistant by holding a small basin and a cup, containing the solution, in it—the end of one rubber tube being in the cup and the end of the other in the basin.

In this picture the middle stopcock only is open, and the syringe is ready for suction.

The advantages of the apparatus, and its method of application over the old ones, appear to the author to be the following:—

1. You get the contents of the antrum alone by suction with no admixture of pus or mucus from the nasal chambers, or naso-pharynx into the glass syringe ready for inspection, before it is emptied into the basin.

2. You do not have to flood the patient in order to have the fluid force its way through the natural opening. You simply pour out into the antrum approximately as much fluid as it can hold. This adds comfort to the patient. (For the sake of demonstration, in one of my early cases, I poured the fluid of the syringe out into the antrum and removed the apparatus. I then introduced the apparatus again and got my fluid back into the syringe by suction.)

3. You leave the antrum dry through suction every time, much the same as Nature does it constantly through the respiratory efforts. By the other methods the antrum is not left dry after irrigations. To make the opening low

down at the floor of the nose will not always help, for the antral floor is many a time lower than the floor of the nose. Besides, the wall of that region is thick and hard, and therefore more painful to break through.

4. You do not have to make a large opening, so the patient can stand the operation much better under local anesthesia.

5. The author believes that you can clear the antrum up in a much shorter time by this method.

6. In subacute cases, where thick mucus and pus were formed, suction appeared to be of more value in draining the antrum.

7. By suction a vacuum and passive hyperemia is formed in the antrum, and that ought to be a distinct advantage.

A NEW METHOD OF TREATING FLAT-FOOT.

By PEREZ B. HOWARD, M.D., NEWTONVILLE, MASS.

MANY of us dislike to see ourselves in print, especially after so many able men have done so much work on this well-known subject, but after some time of experimenting I have a little to add, which perhaps may be of value.

Placing a foot in a shaped plate, steel, leather or felt (the last two become about the same as the first in time) never appeared to me as curative, although they do give relief, as they all act as a splint to the weakened members. While they may be made to fit the arch of the foot at rest they cannot adjust themselves to the changed contour when the arch of the foot is flexed or extended, and tend to hinder by their splint-like effect the free muscular action necessary for a cure.

After having trouble with my own right foot, I decided to try an experiment which seemed to me would give support to the arch in all positions and free play to the muscles, at the same time being perfectly flexible and self-adjusting.

Taking a cast of my foot I made a model and had a rubber factory make up several arch supports or shaped rubber bulbs filled with air. These I covered with leather and tried them out in my own shoe.

Much to my satisfaction, it felt good and I wore it all day, walking on frozen ground to make my calls as my auto was being repaired. At the end of the day it was no more noticeable than the glasses on my nose, and to my relief, I was not nearly as tired as I should have been without the pad and had no pain in my foot and leg.

Since the first experiment I have made several minor changes, but in general the arch above conforms to the arch of the foot below, it fits the shoe, and on the inner side it is reinforced to

prevent bulging. This is encased in leather, which is extended under the heel for an anchor, so to speak, and forward it tapers off just a little in front of the arch support.

The support is made and encased in such a way that the air is held absolutely under the arch of the foot, and as the contour of the arch of the foot changes, the arch support changes also, still exerting on the arch of the foot the same upward pressure. It allows free muscular action all of the time as the foot is flexed or extended in locomotion.

My instructions to my patients have been to get a proper flexible anatomical shoe with a low heel, and if they have a fallen or weakened arch to wear the inflated arch support. They must not expect a cure from this alone, but must exercise their feet by walking every day from three to four miles, being careful not to toe out, and trying to bring the big toe into play. If the patients will do this, I think they will be pleased with the results and the inflated arch may shortly be discarded.

For the acute flat-foot from falls, etc., rest is the best remedy, after which an inflated arch support might help, but my experience in such cases is slight.

My experience with trouble in the anterior arch has been only when there has been trouble, also with the longitudinal arch, and by correcting the latter with an air arch support the former has readily cleared up. A bulb could easily be made though to extend under the anterior arch. In my practice it has not been required.

In regard to the life of such a support, I would say, that we had, at first, some difficulty in making them to stand the weight, but now they do so fairly well, and it is a simple matter to inflate or deflate to any desired elevation. They may also be filled with fluid, in which case they will outlast two or three leather covers and not lose their elevation.

With a few variations in size, they can be made to fit the average feet, and as I have previously said, the inflation may be changed as desired, but as they are more or less self-adjusting, it is surprising how little trouble there is in fitting them.

In closing, I desire to call your attention to a few of the advantages of such a support and which I believe are not combined in any other:—

1. They are very light, even when fluid filled.
2. Flexible in any position.
3. Will not wear the shoes.
4. Do not mat down or lose life, as metal or padded arches do.
5. The pressure in the arch is a shifting pressure and changes with the arch of the foot.
6. They can be used from the first with comfort and relief.
7. The elevation is easily changed.
8. Above all, it allows the muscles and tendons to act freely in all movements of the foot, and thus regain their lost strength.

Reports of Societies.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

SECTION ON GENERAL MEDICINE.

MEETING OF MONDAY, APRIL 26, 1915, AT 8.15 P.M.

DR. JAMES E. TALLEY in the Chair.

REPORT OF A CASE OF SOLITARY ABSCESS OF THE LEFT LOBE OF THE LIVER OF UNCERTAIN ORIGIN CURED BY OPERATION.

By DR. JOHN H. JOYSON AND DR. CLIFFORD B. FARR.

DR. FARR: The subject of the report was a man of thirty-six years of age, born in the Crimea, but nine years resident in this country. He was admitted to the hospital on account of pain in the epigastric region. His illness was attributed to an attack of grip eight weeks prior to admission. He apparently recovered from the acute attack, but four weeks before admission began to suffer with pain in the epigastrium, constant, but increased on movement or when standing. Ingestion of food or water afforded some relief. There was a moderate loss of weight and slight dyspnea. He had never had diarrhea while in Russia, but had had an attack six years ago after coming to this country. It was not definitely dysenteric in type. He had pneumonia three years ago; had also suffered from pleurisy with effusion. Two years ago he had "malaria." The patient had no bad habits. He took an occasional drink. General examination was largely negative. There was slight pallor; long flat chest with some impairment of resonance not definitely localized. The abdomen was scaphoid; the walls were relaxed. In the epigastrium a hard rounded mass continuous with the liver was felt. This moved with respiration and apparently bore no relation to the stomach so far as could be determined by inflating the latter viscus. The mass was dull, the size of a small orange and extended more to the left than to the right of the median line. On palpation it gave a sense of fluctuation as of a tense, fluid containing tumor. It was not very tender. Before operation the mass was thought to be either a tumor or an inflammatory condition. The temperature, pulse and respiration were normal throughout; the urine showed a trace of bile pigment and a few casts; blood count, practically normal. The stomach contents showed a marked hyperacidity; total acidity 128; blood pressure 160 (systolic). At operation a fluctuating tumor was discovered, occupying the left lobe of the liver. This area was walled off with gauze to encourage the formation of limiting adhesions, and three days later the abscess was aspirated and about eight ounces of brownish pus evacuated. Drainage was instituted. The cavity measured $4 \times 1 \times 2\frac{1}{2}$ inches. Examination of the pus showed no hooklets, no amebae and no polymorphonuclear leucocytes. Cultures were also negative. The previous history of diarrhea suggested the possibility of an amebic abscess from which the causative organism had disappeared. Amebic dysentery prevails endemically in the Crimea, but the patient gave no history of any such disease. He was discharged cured on July 23, 1913, about six weeks after operation.

Dr. Jorson: Dr. Farr has given the complete history of the case. I could not satisfy myself before operation of the connection of the abscess with the liver, probably because it sprang from the left lobe. It was more movable from side to side than from above downward. It seemed to increase in size during the patient's stay in the hospital. The process appeared to be progressive and the tissue rapidly breaking down. Examination of the brownish turbid fluid showed few polymorphonuclear leucocytes, but fragmentary tissue characteristic of liver abscess was present. The operative diagnosis was made of solitary abscess of the left lobe of the liver of undefined origin. It was thought an infection may have been present in which the organism had died out. This was not considered very likely, however, because one of the usual causes of the common infections of the liver was present. By exclusion we felt that the condition was an amebic abscess of the liver. The man had had diarrhea and had come from a part of Russia where the amebae are found. It is not improbable that there had been an old amebic infection of the bowel with secondary infection of the liver. The two-stage operation, recommended when the liver is not adherent, was done. It is simple and free from danger. Some 60% of solitary abscesses of the liver are sterile and in about 20% no amebic organism or bacterium is found. My experience with abscess of the liver is very limited. In one case the condition was associated with subphrenic abscess, and in that case the liver broke down secondary to the abscess and the patient died. This was the only case of solitary abscess of this type I have, myself, ever operated upon. I have seen a few others. The first one I saw operated upon was when I was a student. The technic in those days was not very safe; a large vein was wounded and the man bled to death.

A CASE OF OLD ECHINOCOCCUS OF THE LIVER SIMULATING GALL-STONES, WITH X-RAY FINDINGS AND OPERATION.

By Dr. James E. Talley and Dr. John H. Jorson.

Dr. Talley: I have but a few things to say concerning the case. The patient was a woman between 55 and 60 years of age whom I saw first in 1903. She had had nervous prostration and still had attacks of acute nervousness, sometimes becoming unconscious, but without any of the ordinary signs of epilepsy. We had come to the conclusion that these spells were hysterical. I saw her off and on for minor things at intervals for the next two years. She had a good deal of digestive disturbance. I am free to say that if the technic of x-ray examination of gall-stones had been perfected in 1903 as now, she probably would have been skiaographed long ago, for the patient was of the type to suggest the possibility of cholelithiasis. Last spring she saw me again, when she was again suffering from digestive disturbance. She vomited after meals, and was progressively losing weight. Both an Ewald and a Riegel meal showed a low total acidity and no free hydrochloric. She evidently was a case of achylia gastrica, as no new growth was found then or since. She was to return in the autumn, but did not. Meantime she had had one of her spells. Dr. Mulford had advised having a skiagraph made to see whether she had gall-stones and apparently she had. This photographic plate shows a definite picture like gall-stones. She was

admitted to the hospital for operation. Dr. Jorson will describe the findings. Since leaving the hospital she has been in her usual health.

Dr. Jorson: The x-ray examination seemed to show so positively the presence of gall-stones that we decided without hesitation upon operation. Her symptoms among other things suggested cholecystitis,—which she had; but she had also another condition. Operation was done on Nov. 9, 1914. An upper abdominal incision showed marked distention of the gall-bladder surrounded by adhesions, but no stones. The gall bladder was palpated, but no calculi could be found. The routine examination of the stomach and kidneys was made but was negative. On the right lobe of the liver, on the dorsal aspect, there was a yellow area, underlying which was a soft tumor. (Its relative position is shown on the board.) This was apparently the cause of the shadow on the plate. The aspirating needle revealed nothing. Incision revealed a cyst the size of a hickory nut, filled with yellow caseous material, which I removed with a curette. I closed the incision with a couple of sutures and the patient made a normal convalescence. Cholecystostomy and appendectomy were performed. A diagnosis was made of echinococcus cyst. This was confirmed by the finding of the hooklets by Dr. Pfeiffer. I made this diagnosis because I had seen a similar case under Dr. Musser's care posted in the Presbyterian Hospital, in which Dr. Cattell had found the hooklets characteristic of echinococcus cyst. The condition is exceedingly rare in the United States. In this case the apparently positive finding of gall-stones by the x-ray was misleading. The liver is the common seat of echinococcus cyst, 60% being found in this organ.

A REPORT OF TWO CASES OF NEW GROWTH OF THE THYMUS GLAND.

Dr. E. J. G. Beardsley: The first case was that of a girl of seven years, previously considered particularly healthy. In October, 1913, there was noted swelling of the face, neck and head, the tissues appearing edematous, but without pitting on pressure. Slight enlargement of the thyroid and abnormal pulsation of the vessels; slight exophthalmos, and the lids lagged somewhat on downward motion. The heart was displaced downward and to the left and its action was rapid and weak. Physical signs revealed a large mass in the anterior mediastinum. The child's only complaint was a distressing cough. Edema of the chest wall soon became evident and there was general anasarca. A radiographic plate revealed an extensive shadow of a new growth occupying the site of the thymus gland and encroaching upon either lung. Roentgen rays administered in a small town with limited facilities, gave practically no improvement. After a few weeks of treatment the child developed symptoms of nephritis, all the other symptoms became aggravated and the child died in a uremic convulsion, eight and a half months after observation of the first symptoms. Autopsy was denied.

The second patient was a boy of five years of age, previously healthy. In July, 1914, slight puffiness of the eyelids and face was noted. There was slight enlargement of the cervical glands, but no marked evidence of intrathoracic pressure, and the chest was not examined by the family physician. The mother states that the disease began suddenly on Aug. 2, 1914, with marked swelling of the tissues of

the neck. The ears and lips were cyanosed at this time; breathing hurried and labored. There was neither headache, other pain, nausea nor vomiting. Upon swallowing solid food there was a sensation of strangling. Careful physical examination revealed an extensive mass in the anterior mediastinum, and this was confirmed by the radiograph. Under Roentgen ray treatment the improvement of symptoms and the disappearance of physical signs were almost magical. After the first two treatments the child's condition was much improved, and the radiograph showed the disappearance of the greater part of the shadow noted on the first plate. The continued improvement allowed the child to be about the house, but signs of sarcomatosis developed, and the child died about four months after the symptoms were first noted. The second case illustrates the marked relief possible to obtain; while the failure of the Roentgen ray treatment in the first case can be ascribed to the weakness of the x-ray treatment rather than to the treatment itself.

DISCUSSION.

DR. JOSEPH SAILER: In accord with Dr. Beardsley's statement, these tumors are perhaps not so uncommon as supposed. I have seen only two such cases. They were as carefully studied as could be, but in neither case could we obtain an autopsy, and, therefore, the report must of necessity be incomplete. The first case was a woman aged 32 years, sent by Dr. Brown of Quakertown. She had borne five children and had always been a hard-working woman. She was admitted to my wards at the Presbyterian Hospital, complaining particularly of dyspnea. Dr. Brown had recognized a large tumor in the superior mediastinum. It was shown by the x-ray as a large, somewhat irregular mass. It was supposed to be an enlarged thymus, and at my request Dr. Jopson removed part of the gland. We were unable to decide from the pathological report whether or not the growth was malignant. Dr. Jopson decided that operation would be futile. Dr. Newcomet kindly consented to use radium, which was done for a considerable time. I could not determine that there was any physical change in the tumor. Subjectively the improvement was very remarkable. The woman returned to her home against my advice, and in a few weeks the dyspnea returned and she was worse than when she had come to Philadelphia. I advised that she be sent down and suggested the advisability of attempting a section of the sternum for the purpose of relieving pressure upon the trachea, but I have heard nothing further. The second case was a man of twenty-three, admitted to the ward suffering from general hemorrhage. There was bleeding from the gums, nose, gastro-intestinal tract and the urinary tract. A large mass behind the sternum could be palpated, but produced very little discomfort. He had practically no dyspnea and no dysphagia, no sign of compression of the veins or nerves. The various forms of treatment for acute leukemia were given with the usual result; the patient improved and then grew worse and died, not so much the result of pressure upon the trachea as of the gradual progress of the disease and extreme anemia. In spite of our pleading with the family, autopsy was refused. Whether in the future surgery will be devised, making possible the removal of a tumor beneath the superior portion of the mediastinum we do not know. Possibly with the improvement in pul-

monary surgery an operation can be done in cases such as the first with prolongation of the life of the patient. Examination of adjacent lymphatic glands revealed no involvement, and the symptoms were almost exclusively those of pressure.

DR. ROBERT N. WILLSON: It may be of interest to note that in a number of articles that have filtered through in recent German literature reference is made to the coincidence of thymus and thyroid enlargement. An abstract appearing in last week's *Journal of the American Medical Association* brought out two points of value to the internist: (1) The very frequent association of gastro-intestinal derangements with these lesions, indicating a possible origin in gastro-intestinal toxemia (an improper term, but describing the thought); and (2) the control of a considerable number of these cases by large doses of atropin, in the entire absence of surgery. The drug was administered on the basis that it would exert an influence upon the vagotomy which is present in so many of these cases.

FACTORS CONTRIBUTING TO THE DIMINISHED VOCAL RESONANCE OF PLEURAL EFFUSION.

DR. C. M. MONTGOMERY: The mechanism of diminished vocal resonance in pleural effusion, though attributable to simple factors, has apparently never been satisfactorily explained. The factors operative in diminishing the vocal resonance are reflection and diffusion, the former occurring at the junction of the air-bearing collapsed lung with the fluid, the latter between the surface of the lung in contact with the fluid and the external chest surface. The sounds are not diminished as a result of poor conduction, because both fluid and tissue conduct sounds well in the absence of diffusion. There is little sound loss at the fluid-chest-wall junction because the fluid and tissue do not differ greatly in density, or, presumably, in elasticity. The louder vocal resonance over the normal side as contrasted with the side containing fluid, is due to the smaller amount of diffusion on the normal side.

STUDIES IN HYPERSECRETION.

DR. MARTIN E. REHFUSS: In a study of over 100 normal students the average quantity of the residuum of the fasting stomach was 52.14 c.c., a figure considerably in advance of that usually recognized and due to improvement in technique. In studies on normal individuals we found that the response to an Ewald was one of three types, depending on the character, rapidity, and reaction to the stimulus, namely: hypo-, iso-, and hyper-secretory. In 38% of all responses in normal individuals, figures of over 70 total acidity were obtained in some part of the secretory curve. In the hyper-secretory type, there is found normally a definite tendency toward a continued secretion or hyper-secretion, which varies all the way from slight grades to a pronounced secretion for several hours or more. It must, therefore, be recognized that in a certain proportion of individuals to all intents normal, there is a definite hypersecretion merging in pathological cases to a "pronounced hypersecretion."

A point apparently neglected is the "velocity" of the formation of the secretion. There is a pronounced outpouring of the secretion even when the stomach is completely emptied. Results are detailed of the introduction of 0.5% HCL in sufficient quantities (100 c.c.) to stimulate artificially hyper-

secretion in normal individuals. The acidity of the gastric contents is always definitely and persistently lowered and may be followed by secondary stimulation. Whether this is due to the outpouring of a thinning fluid or "Verdünnungssaft" of the Germans or to dilution of fluid of relatively low acidity cannot be stated. It is likewise pointed out that neither atropine, silver, high or low protein diets, salt-free diets, act specifically in every case. But in certain selected cases one or the other occasionally acts in a remarkable manner suggesting possibly several different mechanisms for the production of the condition.

Hypersecretion occurred even of very low acidity in one instance of total acidity 7 and no free acid, of which some 200 c.c. were collected after the meal had completely left the stomach. The dissociation of hyperacidity and hypersecretion is pointed out. It is to be noted that in a large proportion of normal individuals there is a definite hypersecretory tendency and often a "continued" secretion which through the agency of some pathological factor can be markedly aggravated or converted into the most pronounced type of this condition.

DR. J. H. AUSTIN AND DR. O. H. P. PEPPER presented a paper on

BLOOD AND URINARY NITROGEN CURVES AFTER FEEDING.

DR. N. GINSBURG read a paper on

SOME OF THE FACTORS UNDERLYING THE DEVELOPMENT OF GRAVES' DISEASE WITH REMARKS ON VASCULAR OCCLUSIONS OF THE THYROID VESSELS.

Book Reviews.

The Practical Medicine Series. Vol. II. General Surgery. Edited by JOHN B. MURPHY, A.M., M.D., LL.D., F.R.C.S., F.A.C.S. Chicago: The Year Book Publishers. 1915.

This second volume in the Practical Medicine Series for 1915, represents the year's progress for 1914 in general surgery, as summarized from the literature under the editorship of Dr. Murphy. Particular attention is devoted to anesthesia and operative technic. Under the heading of transfusion, the methods of McGrath, Kahn, Davin and Curtis, and Corbett are described in detail. The book, which is admirably illustrated with a colored frontispiece, 49 full page plates and 180 text figures, forms a valuable compendium of recent surgical advance.

Outlines of Internal Medicine. By CLIFFORD BAILEY FARR, A.M., M.D. Philadelphia and New York: Lea and Febiger, 1915.

This volume is intended as a basis for a system-

atic training school course for nurses in internal medicine, and in addition as a work of reference for graduate nurses. In the discussion of diseases, symptomatology, prophylaxis and treatment are emphasized rather than diagnosis. —in short the diseases are described from the natural history point of view. The book is divided into ten parts, dealing respectively with the diseases of the nervous system, of the blood and glands, of the circulatory system, of the respiratory tract, of the digestive tract and peritoneum, of metabolism, of the genito-urinary tract, of the muscles, bones and joints, with diseases due to heat and poisons, and with the infectious and parasitic diseases. The work is well illustrated with seventy-one engravings and five plates, one of the latter being colored. It should prove a serviceable text-book for the instruction of nurses and for their subsequent use while in practice.

Principles of Bacteriology. By A. C. ABBOTT, M.D., Professor of Hygiene and Bacteriology, and Director of the Laboratory of Hygiene, University of Pennsylvania.

This edition is an improvement upon previous editions, although the extreme elementary character of the book is preserved. The added matter is largely upon immunity. In other respects the book cannot be said to be up to date. For instance, nothing is said about the complement fixation test for glanders, the cultivation of spirochetes and the cultivation of the virus of poliomyelitis. The only mention of the *Spirocheta pallida* is in a brief paragraph on the staining by Stern's method, one of the least used and least efficient methods. There are numerous other deficiencies in the book. It is of high school rather than of medical school calibre.

A Reference Handbook of Medical Sciences by Various Writers. Third edition, completely revised and rewritten. Edited by THOMAS LATHROP STEDMAN, A.M., M.D., Vol. V. New York: William Wood and Company. 1915.

This fifth volume continues the third edition of this standard medical encyclopedia, embracing the entire range of scientific and practical medicine and allied sciences. The previous edition was edited by Dr. Albert H. Buck. The present edition, by his able successor, continues the merits of the original. It is primarily the work of a large number of contributors, each an expert in a special field. The book is copiously illustrated by numerous chromo-lithographs and by 733 half-tone and wood engravings. This volume extends alphabetically from head wounds to life insurance, and carries the total number of illustrations in this edition thus far to 3732.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, SEPTEMBER 16, 1915

EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief.*

GEORGE G. SMITH, M.D., *Assistant Editor.*

WALTER L. BURRAGE, M.D., *For the Massachusetts Medical Society.*
FREDERICK T. LORD, M.D.

COMMITTEE OF CONSULTING EDITORS.

WALTER B. CANNON, M.D. ALLAN J. McLAUGHLIN, M.D.

HARRY CUSHING, M.D. ROBERT B. OSGOOD, M.D.

DAVID L. EDSELL, M.D. MILTON J. ROSENBAUM, M.D.

REID HUNT, M.D. EDWARD C. STREETER, M.D.

ROGER I. LEE, M.D. W. W. TAYLOR, M.D.

ADVISORY COMMITTEE.

EDWARD C. STREETER, M.D., *Boston, Chairman.*

WALTER P. BOWEES, M.D., *Clinton.*

HOMER GAGE, M.D., *Worcester.*

JOEL E. GOLDTHWAIT, M.D., *Boston.*

LYMAN A. JONES, M.D., *North Adams.*

HUGH WILLIAMS, M.D., *Boston.*

ALFRED WORCESTER, M.D., *Waltham.*

ROBERT B. OSGOOD, M.D., *Boston, Secretary.*

ERNEST GREGORY, *Manager.* W. M. LEONARD, *Consulting Manager.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

The editor will be in the editorial office daily, except Wednesday and Saturday, from one to two-thirty p.m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

IMMIGRATION AND RACIAL PREDISPOSITION TO DISEASE.

THE effect of environment and climate on racial character, predispositions and immunities has always been recognized, though the reasons therefor have not been clear. With the destruction of the better elements in a race, susceptibility will be increased in the remainder and immunities decreased, commensurate with the emphasis of recessive or undesirable characteristics. In certain of the races and peoples these predispositions and immunities are well marked: The Jews, for instance, have a relative immunity to tuberculosis gained, probably, from long contact with conditions predisposing to it, such as the congestion of the pale, wherein there has been a survival of the fittest, those with some resistant quality—perhaps some antibody. To offset this advantage they are muscularly underdeveloped; they have ptosis and flat-foot, due to a giving way of the musculature at

points of pressure. They are prone to congenital physical defects, and have highly sensitive nervous systems. They are the chief sufferers from diabetes. Wilson (*Medical Record*, Oct. 2, 1912) showed that there has been a constant and commensurate rise in the diabetes incidence in New York City, keeping pace with the increase of the Jewish population therein—a striking example of the effect of alien accession on local morbidity. The diabetes in them may be the results of constant intermarriage among themselves—a racial consanguinity—which has a tendency, even in animals, to produce a general constitutional instability. This same race, on the other hand, possesses an indisposition to alcoholic intemperance. On the other hand, likewise, a mixture of this race with the physically dominant races here produces a fine type and tends to eliminate their recessive characteristics (Friedman, *J. A. M. A.*, March 9, 1912.)

The Greeks are subject to various forms of infantilism, especially arrested sexual development. They are particularly prone to spinal meningitis. The Armenians and Syrians are particularly prone to trachoma, and very susceptible to typhus fever, the sporadic types. The Italians age prematurely and have a marked tendency to arterio-sclerosis. Malaria, hookworm and pellagra are common among them. When transplanted from their own soil they are subject to tuberculosis. Rickets and osteomalacia are relatively common among them. The Turks are very susceptible to mumps. The Spanish, Portuguese and Basque sheep-herding people are prone to contract anthrax.

The Swiss tendency to goitre and strumipriva is well known. It is a water-borne condition, not due to animal contamination, but probably to the presence of certain toxins, which, however, are destroyed and the water made fit by boiling to 80 C. In the Germanic and Scandinavian races there is a marked tendency to albinism. The proneness of the Germans to myopia is great, indeed, even to 60% of their population. Leprosy is, for some reason, present in the Scandinavian countries, but is well under control. The Scandinavian races do not survive in warmer climes. Their settlements in the Southern states are now all gone, while those in the Northern states are thriving. The intemperance of the Irish seems due to food poverty and general poverty. For the same reason they have a proneness to tuberculosis, rickety bone deformities and

teeth caries. Yet these recessive qualities soon disappear under favorable environment.

The negro is very prone to tuberculosis, to rickets and hookworm. He enjoys a marked immunity to trachoma but seems to be developing a susceptibility to leprosy. The yellow race is susceptible to trachoma, leprosy and beri-beri. The red race is markedly susceptible to trachoma and tuberculosis, and, indeed, it is from the latter that it is dying out. In general, all aboriginal races are susceptible to the eruptive diseases, especially measles, by which whole communities may be wiped out.

To bear in mind these various susceptibilities and immunities will be of aid to medical officers engaged in the protection of the public health, yet these conditions have a larger significance than merely the detection of individual cases. Active cases are few, but every immigrant carries the potentiality which may nevertheless leave its mark with us who must needs act as a melting pot. It is important to consider the effect of a large migration with its native susceptibilities on the peoples here. Will the dominant qualities of the habitant race overcome the recessive qualities of the migrating races, not merely socially and economically, but racially; that is, physically and mentally? Will the large admixture of these races reduce the native standard and introduce new susceptibilities? It is a real question of preparedness. Are the races here constitutionally prepared to overcome and assimilate a great number of recessives?

SURGICAL DRAINAGE WITH STEEL SPRINGS

So much misery has already been the fruit of the European war and so much more will undoubtedly come to pass before peace is declared, that it would be surprising indeed if there were not a moiety of good discoverable here and there. When the smoke clouds have finally rolled away and the nations settle down to count up the cost, it seems probable that in spite of the heavy death roll of the military surgeons, the medical profession, and especially the surgical branch of it, will have benefited most by the wholesale carnage; for in the arena of war are opportunities which have never before existed in the history of the world for observing surgical injuries and testing out methods of treatment.

Cases which in civil practice are considered

rare, the Red Cross surgeon sees every day and he is able to reckon up his operations by hundreds instead of one or two now and then. Not always does he find himself adequately provided with the tools of his profession either, and often amputations must be done, abscesses opened and wounds dressed in a hurry and under fire, so to speak. Small wonder that the medical mind, stimulated by the constantly recurring emergencies of war and impatient with methods which formerly seemed good enough, is constantly devising new methods of treatment which, if they are successful on the battlefield and in the field hospital, will be the common-places of the surgical education of tomorrow.

One of the most recent inventions, if we may term it such, is a new method for draining wounds, originated by a German surgeon, Dr. Tiegel. He had become dissatisfied with present methods of draining, especially with the familiar disadvantages of gauze drains; that is, that after being in the wound a short time they dam up discharges and thus may form pockets of pus, and that when these drains have been saturated with some antiseptic solution they keep this germicide too long in contact with the tissues, tending to devitalize them. Dr. Tiegel's method is the use of a small, rather weak steel spring placed between the edges of the wound so as to hold them slightly apart. At each end of the spring is a small, oblong plate of metal which prevents laceration of the tissues. The wound is thus held open and if possible the patient is placed in such a position that gravity assists in drainage. After twenty-four hours the spring is removed. The originator of this method has found that there is no pain while the spring is in place although its removal may be attended by some discomfort. This sort of drain does not interfere with the natural tendency of the cavity to collapse as does a gauze drain, and so obviates what sometimes happens with the latter kind of drain, *i.e.* the establishment of a cavity with definite walls which has to be filled up with granulation tissue.

VACCINATION OF THE WOUNDED.

HOWEVER much we deplore the suffering attendant upon war, we of the medical profession must keep ever before us the prospect of being called to help our own country should it be forced into conflict. It behooves us, therefore, to benefit by the experiences of our European col-

leagues who are every day learning fresh facts about the treatment of wounds. This war has presented problems which military surgeons have never before had to solve or at least not in such quantity, the poisoning of troops by noxious gases, hysteria infecting whole groups of soldiers, injuries due to the wind of explosives.

As might have been expected, serum therapy, that youngest offspring of clinical medicine, is having a wholesale chance to demonstrate its efficiency. Whole armies are vaccinated against typhoid and smallpox with a consequent complete protection against these scourges. We may watch with the most interest, however, the employment of vaccines in wounds, for their efficacy here is yet a mooted question, and certainly a war of such dimensions as the present one will give us a sufficient number of cases from which to generalize.

An English physician, Dr. Tidy, has given us¹ a preliminary report on the use of vaccines in wounds. He has not found that any miraculous results follow their use, but is inclined to believe that they have on the whole been of some use. It has been his custom to wait several weeks before using vaccines in order to give natural healing processes a chance. Then he begins with small doses of vaccine and gradually increases these. Autogenous vaccines are used if procurable, otherwise mixed vaccines approximating as closely as possible the organisms responsible for the infection in question.

Dr. Tidy states that the temperature is the most reliable guide in the use of vaccines. There should be no elevation of temperature of over .5° following an injection. The best result is a steady fall in the temperature curve. Sometimes the patient complains of various constitutional symptoms such as headache, nausea and malaise and there may be a temporary aggravation of the discharge, but according to Dr. Tidy, these symptoms may be ignored if the temperature continues to drop steadily. He does not approve of giving vaccines at all in mild cases and says that they should never be given within thirty-six hours of an operation on an infected case.

¹ *The Treatment of the Wounded by Vaccines.* By H. L. Tidy, M.D., *Lancet*, August 14, 1915.

MEDICAL WAR ARTICLES AND CORRESPONDENCE.

THE importance and interest of the European War, especially in its relation to medical affairs,

are particularly well illustrated by Dr. Mixer's article and by the communications which we are able to present in other columns of this week's issue of the JOURNAL, from our special correspondents in three different fields of action. Dr. Mixer's experiences in France may be regarded as representative of the best surgical opportunity to be obtained by American surgeons serving in that country during the present war; and his account of them, admirably illustrated by original photographs, presents most vividly the conditions prevailing at a hospital of the type of the Chateau Annel and at Juilly. The first of our correspondents presents, in his familiar and attractive style, the medical and general situation near the Italian frontier, among the valleys of Savoy. The second, who has been serving with the American Red Cross mission at Budapest, presents other aspects of war conditions in Italy and Austria than those with which readers of the JOURNAL have already been informed by previous correspondents. The third, an editor of the JOURNAL, discusses aspects of his experience on his journey through France towards the hospital where he is at present in service. In next week's issue of the JOURNAL we shall be able to publish a further communication from Dr. Smith describing his work at this hospital. The JOURNAL values most highly its opportunity to present to the medical profession in America such communications from reliable members of that profession now sharing in the momentous experiences of the European war, and desires herewith, in its own behalf and in that of its readers, to extend grateful acknowledgment to its past and present contributors and correspondents and to those who, in the future, will continue to supply these first hand accounts of events whose ultimate importance is as great as their present interest.

MEDICAL NOTES.

NEW YORK WEEKLY MORTALITY REPORT.—According to figures supplied by the Department of Health there were during the week just ended twenty-four more deaths than during the corresponding week of last year. The exact number of persons that died during the past week was 1361, with a rate of 1223, as compared with 1286 and the rate of 12.01 for the week ending August 29, 1914.

The important feature in the report for the past week is the increased mortality from ty-

phoid fever. Of the 21 deaths from this disease last week, 12 occurred in the Borough of Brooklyn and 41 new cases reported in that Borough as against 29 in the remaining four boroughs. The heaviest mortality occurred in the 8th Ward of Brooklyn.

Of the contagious diseases whooping cough was the only one that showed an increase. The deaths reported from diarrhoeal diseases under 5, were two more than during the corresponding week of last year. Considering the increase in population this amounts to a material reduction in the rate.

The death rate for the first thirty-five weeks of 1915 is 13.64 as compared with 14.10 for the corresponding period of 1914.

ROCKY MOUNTAIN SPOTTED FEVER.—Since January 1st, 1915 there have been reported by the United States Public Health Service a total of 562 cases of Rocky Mountain spotted fever with 36 deaths. Idaho had the largest number of cases, 360 in all. The occurrence of the disease in other states is as follows: Wyoming, 59 cases; Oregon, 46 cases; Montana, 34 cases; Utah, 31 cases; Colorado, 14 cases; Nevada 8 cases; Washington, 6 cases; California and South Dakota each two cases. Montana with 34 cases reported that 22 occurred in territory previously uninfected, which represents a spread of the disease in the southeastern part of the state. Two cases occurred in South Dakota, the first ever recorded from that state. They probably represent the same extension of the disease in a northeasterly direction from Wyoming from the southeastern part of Montana. Three of the cases reported from Oregon represent an extension to the northwest of that state.

PROGRESS OF THE IMPERIAL CANCER RESEARCH FUND.—The research work of the Imperial Cancer Research Fund has, as naturally might be expected, been considerably affected by war conditions. In view of the demand by the War Office for highly trained investigators, Dr. Russell, Dr. Compton, Dr. Bullock and Dr. Singer have entered the service. Fortunately, on the outbreak of the war, several Japanese doctors who had been conducting researches in Germany applied for permission to work in the laboratories. Two of these doctors, Dr. Tsurumi and Dr. Takahashi, received appointments and have been carrying on valuable researches and assisting the Director in routine work. Dr. Kenneth Taylor, of Minnesota, joined the laboratories as a voluntary worker, but was soon called to join the American Ambulance at Paris. In February, Dr. F. C. Wood, Director of the George Crocker Special Research Fund, New York, offered to assist the Laboratories in the event of the staff being called for service, by taking over for the time being the material, and if necessary, the laboratory servants with full salaries. This offer was cordially acknowledged

with the information that it was hoped the staff would be able to keep the routine work of the Laboratories going without interruption.

FUMIGATION AS A METHOD OF DISINFECTION.—The American Public Health Association met in Rochester, N.Y., for its forty-third annual meeting on September 6. The fifteenth annual conference of Sanitary Officers of New York State and the annual meeting of the New York Sanitary Officers Association were held simultaneously. One of the subjects under discussion was the question of fumigation of houses after contagious diseases as a means of disinfection. The JOURNAL noted in a recent issue the decision of the Boston Board of Health to discontinue the practice of fumigation as useless, inefficient as a method of killing germs and merely resulting in a waste of public funds. The practice has also been discontinued in Providence, R. I., and the attitude of the American Public Health Association towards its general condemnation will, no doubt, result in its abandonment by most cities and towns. If, instead of relying on fumigation, householders will resort to fresh air and sunlight and soap and water cleaning to destroy lurking disease germs and will guard more carefully against infection by personal contact, probably fewer cases of spreading infection will result than would be the case if dependence were placed on fumigation as ordinarily performed.

PREVALENCE OF MALARIA, MENINGITIS, POLIOMYELITIS, SMALLPOX AND TYPHOID.—In the weekly report of the United States Public Health Service for August 27, 1915, it is noted that during the month of July, 1915, there were in Massachusetts twenty-seven cases of malaria, twelve of cerebro-spinal meningitis, eight of poliomyelitis, two of smallpox and 170 of typhoid fever. During the same period there were seventy-three cases of malaria in New Jersey; and in Ohio eight cases of meningitis, twenty-four of poliomyelitis, 129 of smallpox and 292 of typhoid. There were 217 cases of typhoid in South Carolina, 128 in New Jersey, ninety-five in Michigan, sixty-nine in Washington, forty-three in Minnesota and thirty-six in Louisiana.

INCREASE IN COST OF ANTIPYRINE AND OTHER DRUGS.—In previous issues of the JOURNAL we have noted from time to time the progressive advance in the cost of various drugs on account of the interference with their supply by the war. One of the most rapid increases has taken place in the price of antipyrine, which on June 3 sold at \$6.50 a pound. On July 21 this price was raised to \$13.00 a pound and on August 20 to \$20.00.

A part of the increase in the cost of drugs since the outbreak of the European war has been genuinely due to interference with the sup-

ply; a part also has been due to speculation, which reached its climax in the latter part of August, 1914. The quotations of that date were generally higher than at present, with the exception of certain important products. On May 1, 1915, however, there began a second rise in prices which has continued almost steadily to the present date. On August 30, 1915, the prices quoted per pound for certain of the important drugs were as follows: opium, \$7.50; corrosive sublimate, \$1.45; thymol, \$11.00; balsam of Peru, \$3.75; sandal wood oil, \$6.00; belladonna root, \$1.75, and ipecac, \$2.50. The corresponding prices on July 1, 1914, were: opium, \$6.85; corrosive sublimate, \$.55; thymol, \$2.15; balsam of Peru, \$1.60; sandal wood oil, \$5.10; belladonna, \$.11, and ipecac, \$1.50. On July 1, 1914, cod liver oil sold for \$19.00 a barrel. It now costs \$65.00 a barrel.

EUROPEAN WAR NOTES.

HEALTH OF GERMAN SOLDIERS.—Report from Berlin by way of London on September 2 states that the health of German troops on the various battlefronts is excellent. Dr. Otto von Schjerning, surgeon general of the German army, in a recent report stated that cases of typhus fever have occurred but rarely, though prior to the war the disease was endemic in some of the occupied districts.

The typhus was successfully combated by providing the soldiers with sterilized water, more than 300 portable apparatuses for boiling, cooling and filtering drinking water being employed. Each of these was capable of preparing 200 gallons hourly. The military physicians systematically isolated all cases, not only among the German troops, but also among the civil population of the occupied districts. Anti-typhus vaccination of the soldiers was also generally performed since the outbreak of the war, which was impossible during the mobilization period.

Along the Russian front Asiatic cholera has also constituted an important menace. Many cases were found in the area recently occupied beyond the River Vistula, but nowhere has it become epidemic. Between July 18 and 31 there were 215 cases of this disease among Russian prisoners in Germany and sixteen cases among German soldiers. This disease, also has been successfully controlled by inoculation and by the use of sterilized drinking water. In Austria, conditions are not so favorable. Report from Rome by way of Paris on September 7 states that during the last three weeks of July there were in Austria 1885 cases of typhus fever and 7427 cases of Asiatic cholera with 3395 deaths.

CASUALTIES AMONG PHYSICIANS IN SERBIA.—In a recent issue of the *Journal of the American Medical Association*, are presented statistics showing that of 387 native Serbian physicians

alive at the beginning of the war, 93 have died, 82 of them from typhus fever. There have been 35 deaths among foreign physicians in Serbia during the war of whom four were American, three British, and two Belgian.

WAR RELIEF FUNDS.—On September 10 the totals of the principal New England Relief Funds for the European War reached the following amounts:

Belgian Fund	\$271,461.37
French Fund	14,093
Italian Fund	5,676.20

A CANADIAN SURGEON IN FRANCE.—The following extracts from the letter of a Canadian surgeon of the Royal Scots to his family, recently published in the *Quebec Chronicle*, illustrate some aspects of medical service at the front in France:

"I was glad to get the letters from home, but was sorry to note you were feeling so anxious. You can rest assured that living here is much safer and much less exciting than the concentration of our moments into one letter would indicate. Don't worry about me. I select a nice secluded spot, and get it well fortified."

"We had a little bit of excitement last night when we exploded a mine and occupied the crater. We lay in our redoubt and listened to the merry shriek of the bullets going well over our heads. None of our men were wounded, but I think we got a number of Germans. For five weeks we hadn't one man killed in our battalion."

"We have had hot baths in good (enamelled) bath-tubs every time we have been out of the trenches, hot water turned on. We have better meals in billets than even in the hospital. I have played on three cricket matches and took part in sports Dominion Day."

"I used most of the money sent me to provide the men in hospital with newspapers and for prizes at the sports, as I thought this would be the most beneficial use to put it to at the time. These kinds of things are very welcome, as they are a change and any way, nothing is too good that will give pleasure and relaxation to our men who are doing the fighting so effectively."

"My dressing station is in a combination of a well-built log cabin and a dugout. Quite a large hill protects us from the Germans. At first the sound of the guns, both ours and theirs is rather trying, but it took me only a couple of nights to get accustomed to them, and now I can sleep through almost anything."

"I see the church has put in a protest against sending cigarettes to the soldiers. I admire their spirit, but not their judgment. With very few exceptions, the clergymen in our division smoke out here, and do not think it is because they have fallen from their ideals, but because they realize the value of what proves to be, for them, a soothing, refreshing pleasure, whose harm under these circumstances of outdoor life and exercise is

more than neutralized by the general benefit in the way of restful contentment.

"We had a beautiful time in our billets. I was billeted in the Curé's house. He was a genial soul, and did not seem to be at all disturbed by the fact that his house has been occupied for the past eight months by soldiers, and that the Germans were within a very short distance of his beloved church. He had six dogs, a fine garden, and a good library, and was happy in these.

"My stretcher bearers are splendid, and are the heroes *par excellence* of the game, I believe." "The heel protectors and socks have been most useful. The men come in with sore heels, which do not get a chance to get quite well in billets, but with the protection of your heel leathers they get a better chance, and I could use more of them."

"The men are in very fair condition, and although most of the glamour and glory of war has been shelled out of their minds they are determined to see this thing through."

"It is fine working with them, and being able to feel that you can do something for the men who are really doing the hard and dangerous end of the business."

STATUS OF AMERICAN RED CROSS RELIEF.—The American Red Cross has recently received various inquiries indicating a lack of public understanding of the terms under which its relief work is performed in the time of war. The following statement has been issued in the public press defining these terms and the status of the Red Cross in relation to the government of belligerent countries:

"There is an international treaty, a very explicit law, a presidential proclamation, and duly promulgated orders of the War and Navy Departments relating to the furnishing of volunteer aid to the sick and wounded of armies in time of war. It apparently is not fully realized that war relief work must be accomplished under definite regulations; that a precise plan of action was long ago adopted, and that a nation-wide, officially recognized and chartered relief organization, with departments designed to meet every phase of war relief work, exists.

"The conduct of war is regulated by certain well-established and recognized rules that are usually designated as "the laws of war" which comprise the rules, both written and unwritten, governing carrying on war, both on land and at sea. Should there ever come a time when the United States would be involved in war it would be imperative to enforce with the utmost stringency the law, and the executive and departmental orders governing the use of the Red Cross emblem and the functions of the Government's chartered supervision and systematized volunteer relief association.

"All volunteer aid must come under the direction of the American Red Cross in such a contingency to carry out the obligation of the United

States under the Treaty of Geneva, to fulfil all requirements imposed by Congress, to secure efficiency under centralized authority and trained organization in close affiliation with the Army and Navy Medical service, and finally to safeguard the American public against fraud and abuse.

"It should be understood that the surgeons general of the United States Army and Navy are appointed by the President of the United States to represent these departments in relief work. They are members of the American Red Cross executive committee, and chairman and vice chairman, respectively, of the War Relief Board.

"All accounts of the American Red Cross are required by law to be audited by the War Department and an annual report, also required by law, detailing the activities of the organization, is made to Congress by the chairman of the central committee. It may be seen from this that the American Red Cross machinery would be set in motion at once and that its activities would be definitely coördinated with the legislative and executive work of the Government in time of war. Merely as an example of its preparedness in one branch of its organization, there are 6000 enrolled American Red Cross graduate trained nurses who have been accepted by the War Department as the Army Nursing Reserve Corps.

"The War Department and the Navy Department long ago formulated regulations governing completely the duties and functions of the American National Red Cross with reference to rendering aid to the land and naval forces in time of actual or threatened war. The sign of the Red Cross is protected by law and the fraudulent use thereof is punishable by fine or imprisonment or both.

"President Taft in 1911, by proclamation to the Army, stated briefly the relations that must exist between the military departments of the Government and volunteer relief in the event of war. General Orders, No. 170, War Department, 1911, publishes the proclamation, stating in effect that the American National Red Cross is the only volunteer society authorized by this Government to render aid to its land and naval forces in time of war; and that any other society desiring to render similar assistance can do so only through the American National Red Cross; that to comply with the requirements of Article 10 of the International Red Cross Convention of 1906 (revision of the Treaty of Geneva), that part of the American National Red Cross rendering aid to the land and naval forces will continue a part of the sanitary service thereof."

BOSTON AND NEW ENGLAND.

TYPHOID AT GRAFTON STATE HOSPITAL.—In the issue of the JOURNAL for August 26, 1915, we noted the recent occurrence of an outbreak of

typhoid fever at the Grafton State Hospital. In the monthly bulletin (No. 12) of the Massachusetts Board of Insanity for August, 1915, the superintendent of the Hospital reports that the epidemic proved to be the result of two carriers, both patients, one of whom had the disease ten years before and the other five years before. All the twenty-six cases which occurred were among women patients. Prophylactic anti-typhoid inoculation was administered to 1480 patients and 369 employees. There were two fatalities among the typhoid cases.

AWARD OF AMERICAN MEDICINE GOLD MEDAL.

—It is announced that the award of the American Medicine Gold Medal for the year 1915 has been conferred upon Dr. Rupert Blue, Surgeon General, U. S. Public Health Service, as the American physician who, in the judgment of the donors, has performed the most conspicuous and noteworthy service in medicine and surgery during the past year.

BOSTON SCHOOL PHYSICIANS TO BE CONTROLLED BY THE SCHOOL BOARD.—On September first the Boston School Board took formal charge of the examining physicians for the schools, hitherto under the jurisdiction of the Board of Health. Physicians receiving appointments as school physicians must now pass a civil service examination. This examination will take place on September 23.

BOARD OF HEALTH OF THE CITY OF PORTLAND, ME.

—The report of the Board of Health of Portland, Me., for the year 1914, records that among contagious diseases, typhoid fever leads in number of cases. There were 217 cases with 20 deaths. Of scarlet fever there were 126 cases with three deaths; diphtheria 105 cases with 11 deaths; eight cases of smallpox and three of infantile paralysis. Of all causes of death, nephritis, with 120 deaths, leads, pneumonia coming second. The total number of deaths was 996 and of births 1,460.

DEPARTMENT OF HEALTH TO BE NOTIFIED OF DIARRHEAL DISEASES.—The following letter has been mailed to every physician in the city of Boston by Dr. Francis X. Mahoney, Commissioner of Health:—

"The Health Department wishes to use all the means in its power to reduce the number of cases of dysentery and all deaths from this cause among infants. It is now required by law that all cases of dysentery be reported to the department at once in writing, and this matter is called to your attention, in order that there may be no chance of a misunderstanding. It is not the intention of the department to interfere in any way in the care of these cases by the physicians, or to quarantine them. It is highly important that immediate notification be made of all diarrheal conditions among in-

fants, that the milk supplies and the sanitary conditions of the homes may be investigated. "Postals for notification of reportable diseases are furnished free."

RESULTS OF MEDICAL INSPECTION IN BOSTON SCHOOLS.—The success of thorough inspection of school children as to eyesight and hearing defects is shown by a comparison of the results of inspection in Boston schools for the years 1907 and 1914. In 1907, of the 83,909 children examined 31.5 per cent. were found to have defective vision, and 8.13 per cent. defective hearing. In 1914 only 12.36 per cent. were defective in vision and 2.7 per cent. in hearing.

ADEQUATE MEDICAL INSPECTION FOR RURAL DISTRICTS.—Dr. Merrill E. Champion, State District Health Officer, in a recent address, called attention to the pressing need of adequate medical inspection for rural schools and the difficulty under present arrangements of such inspection being provided. He urged the appointment of a full-time medical inspector and a trained nurse and that a living wage might be provided, he suggested the banding together of several towns in the support of a physician and a nurse who could by this means afford to devote their whole time to the care of the school children.

Obituary.

CARLOS J. FINLAY, M.D.

DR. CARLOS J. FINLAY, of Havana, Cuba who died on August 21, 1915, in Savannah, Ga. was born at Puerto Principe, Camaguey, Cuba in 1833. After obtaining his early education at the Lycée de Rouen in France, he studied medicine at the Jefferson Medical College in Philadelphia, from which he received the degree of M.D. in 1855. Returning to Cuba, he began the general practice of his profession at Havana and soon became one of the leading physicians of that city. As early as 1881 he became a delegate from Cuba to the International Sanitary Conference held at Washington, D.C., in that year.

It was at this time that Dr. Finlay first announced his theory of the transmission of yellow fever through the bite of the mosquito. He had observed a correspondence between the autumnal increase of yellow fever and the abundance of mosquitoes at that period, whereas during the summer, when mosquitoes were few, the disease was not extensively prevalent. He therefore began a series of experiments which ultimately led to the great discovery of the methods of transmission and control of yellow fever.

In Augustin's "History of Yellow Fever" (New Orleans, 1909) Dr. G. Farrar Patton writes as follows of Finlay's early work in the

important investigation: "We cannot pay too high a tribute to the acumen of Dr. Carlos J. Finlay, who, as far back as 1881, not only advocated with absolute confidence the doctrine that yellow fever is conveyed by the bite of a mosquito, but correctly designated, as was proved some years later by the experiments of the United States Army Commission under Dr. Walter Reed, the particular mosquito, and the only one, so far as known, by which the disease is transmitted to man. Unfortunately, Finlay did not at that time, have the advantage enjoyed by later investigators, of deriving helpful suggestions from the knowledge of the rôle played by the mosquito in malarial fever; but reasoning on the simple doctrine of direct inoculation, he thought that the proboscis of the mosquito biting a patient ill with yellow fever, became contaminated with the virus of the disease, which in turn was directly infused into the blood of other persons subsequently bitten by the same mosquito, thereby conveying the disease to those who were not immune. For reasons now well understood, the experiments made by Finlay to prove his theory were uniformly unsuccessful, but he remained unshaken in his belief that the particular house mosquito formerly called *Aedes fasciatus* and now named *Aedes triseriatus*, which he observed to be invariably present in connection with yellow fever, was the active agent in its transmission, and, unlike many pioneers who have advocated truth before the world was ready to receive it, he lived to see his faith triumphantly vindicated." If Finlay could have ascertained what Carter later determined, that a definite period of time must always intervene between infecting and secondary cases, he could hardly have failed to keep some on his infected mosquitoes over that period. It was impossible, however, to make this observation in Havana where the disease was continuous. For twenty years Finlay was regarded as a hopeless visionary until the work of Reed and his associates in 1900 and 1901 demonstrated the accuracy of his hypothesis. Finlay's position prior to their demonstration is, perhaps best stated in his article on "Mosquitoes Considered Transmitters of Yellow Fever and Malaria" in the *New York Medical Record* (1899, Vol. 55, 737).

In one of his monographs Dr. H. R. Carter of the United States Public Health Service, refers to Finlay's work on yellow fever as "a very beautiful piece of inductive reasoning." His experience was the unusual one of a scientist who, discovering a truth, but unable to demonstrate it, lived to see his belief established by the work of others. As Patton in his article concludes, "It takes away nothing from the perishable fame of Reed and his collaborators to give Finlay due credit for abstractly reasoning out a great truth and for so steadily upholding his belief despite his inability to prove it." In 1902 Dr. Finlay was appointed chief sani-

tary officer of Cuba and in 1903 he again went to Washington as the Cuban delegate to the International Sanitary Conference in that city. He remained as sanitary officer of Cuba until his retirement in 1908. Since 1909 he had been honorary president of the Junta Nacional de Sanidad Beneficencia.

Dr. Finlay was a member of the Havana Academy of Sciences, the Sociedad de Estudios Clínicos de Havana, the Société Scientifique of Brussels, the Royal Society of Arts of London, the College of Physicians of Philadelphia, and a member of the American Public Health Association. He was also a Fellow of the Society of Tropical Medicine and Hygiene of England, an honorary member of the American Society of Tropical Medicine, and the Société de Médecine Tropicale of Paris, and a corresponding member of the Académie de Médecine of France.

Miscellany.

MONTAIGNE ON THE MEDICAL EFFECT OF IMAGINATION.

In the twentieth chapter of the first book of his essays Montaigne quotes the two following cases illustrating the medical effect of imagination in the relief of bodily afflictions:—

"Some man peradventure, by the effects of imagination leaveth the pox or Kings evil heere, which his companion carrieth into Spaine againe: loe heere why in such cases men are accustomed to require a prepared minde, wherefore doe Physitians labour and practise before hand the conceit and credence of their patients, with so many false promises of their reeoverie and health, unlesse it be that the effect of imagination may supple and prepare the imposture of their decoction? They knew that one of their trades master hath left written, how some men have been found in whom the only sight of a potion hath wrought his due operation: All which humor or caprice is now come into my minde, upon the report which an Apothecarie, whilome a servant in my father's house, was wont to tell me, a man by knowledge simple, and by birth a Switzer; a nation little vaine-glorious, and not much given to lying, which was, that for a long time he had knowne a Merchant in Tholouse, sickish and much troubled with the stone, and who often had need of glisters, who according to the fits and occurrences of his evil, caused them diversely to be prescribed by Physitians. Which being brought him, no accustomed forme to them belonging was omitted, and would often taste whether they were too hot, and view them well, and lying along upon his bed, on his bellie, and all complements performed, only injection excepted, which ceremony ended, the Apothecarie gone, and the patient lying in his bed, even

as if he had received a glister indeed, he found and felt the very same effect, which they doe that have effectually taken them. And if the Physician saw that it had not wrought sufficiently, he would accordingly give him two or three more in the same manner. My witness protesteth, that the sicke man's wife, to save charges (for he paid for them as if he had received them) having sometimes assaid to make them onely with luke warme water, the effect discovered the craft, and being found not to worke at all, they were forced to returne to the former, and use the Apothecarie."

"A woman supposing to have swallowed a piume with her bread, cried and vexed her selfe, even as if she had felt an intolerable paine in her throat, where she imagined the same to sticke; but because there appeared neither swelling or alteration a skilfull man deeming it to be but a fantasie conceived, or opinion, apprehended by eating of some gretty peece of bread, which haply might pricke her in the swallow made her to vomit, and unknowne to her, cast a piume in that which she had vomited. Which the woman perceiving, and imagining she had cast the same, was presently eased of her paine."

Correspondence.

PARIS LETTER.

THE REVERSE OF THE PICTURE.

(From Our Special Correspondent.)

PARIS, August 21, 1915.

Mr. Editor: I have recently spent a couple of weeks up in the high valleys of Savoy, on the Italian frontier, and both on the voyage there and back, and during my stay in that beautiful though little-frequented region, I have been able to observe a side of this war so far entirely unknown to me: how it really affects the French people, and what they think on the subject,—for it is a time-honored saying that Paris is not France, whatever we who live in the capital may believe in that respect. Both going and coming the trains and stations were simply swarming with the military; not only was every seat taken, but even the corridors were packed, while as for the badlam at such centres as Dijon, for instance, it beggars any attempts at description. The French soldier is quite unrecognizable now; this year in the open, combined with a light greyish-blue uniform, and the quiet but manifest confidence in himself that he has regained, have made him into a transformed being. A large portion of these men were going home for the first time since the outbreak of the war, on harvest leave; there was then every justification for noisy conduct, horse-play and perhaps bragging. But we saw practically nothing of the sort. The men were loaded down with rifles, knapsacks, side-bags, wine flasks, and cartridge-pouches, until we simply didn't know where to put things; but good-humor overcame every obstacle, each one did his best; and we all ate, drank and talked together as though we had pigged it in the same trench all winter. The usual stand-offishness of the French when travelling has vanished into thin air; people now speak to each other at a glance, before they are really seated. But in spite of all this good feeling, and the natural rejoicing at seeing home

once more, there was no noise; these men realize that this war is a deadly business, that it is still anything but finished; and they are consequently in no mood for merriment.

Besides, this looking death in the face night and day for month after month necessarily changes a man's nature; we remarked over and over again the seriousness of all these men, and the total disappearance of the foolish *blague* that used to be such a trying feature in an ordinary French crowd, where men of 25 would be performing antics that could at best be tolerated in boys of six or eight.

We had quite a number of wounded with us, chiefly men discharged from the ambulances and on their way home to convalescence, many with a limb gone, others on crutches, and all with the thin, white, drawn face that everyone now knows so well, and that tells of months' of suppuration. The behavior of the crowd to these poor fellows was a perpetual delight; to have been wounded in the war makes you *ipso facto* everyone's brother. To the other chaps in blue you are at once *mon vieux*, and addressed in the second person; to the ladies, *mon ami*, without further ceremony. A tall, pale artilleryman, with a stiff knee, crutches and two medals, appears at the door. The compartment is crammed, but that makes no difference; everybody instantly hops up and lends a hand, he is hauled in bodily: "*Donnez-moi tes béquilles*," "*Mettez-vous là, mon ami*"; and one or two sturdy chaps are unhesitatingly hustled out into the corridor already packed to death, while the new arrival is made comfortable, though profuse with apologies. Then we offer cigarettes, our wine-bottles, or fruit, and get his story out of him. The entire scene is simply a revelation, and rather makes one think that human nature may have some excuse for existence after all. When you think of the reception anyone would have got only a year ago, if he had tried to squeeze into a compartment that already had its proper complement!

We finally branched off onto a side line, and there the crush decreased, although the gentlemen in pale blue were still everywhere to the fore; many of the uniforms were sadly faded by hard service; but all had been cleaned of the trench-mud as far as possible so as to present a creditable appearance on arriving home. In our compartment were three men of the Reserve, smoking and passing around the practical French army-flask, the one with the little air-tap that enables you to extract its contents without going through the asphyxiating slobber usually associated with drinking from a bottle. The wine in this district is very cheap and only slightly alcoholic, and the soldiers get it at the stations for about cost-price. One of these men offered me his flask, which I courteously declined, not wishing to diminish the supply available until the next halt; but bless you! that didn't answer, by any means. The excellent chap's feelings were badly hurt, and he remarked in dignified remonstrance: "I did not suppose you would refuse a *brave soldat* when he offered you the wine of his country." So I made amends and harmony was restored.

We were to spend the night at Cluny, which is mentioned in the books as having been the intellectual capital of Europe in the 12th century, the great Benedictine abbey that at one time had some 2000 religious houses dependent on it! This we felt we ought to see. But it turned out rather a disappointment, since here, as pretty much all over France, there again appears the utter lack of sentiment, not to say evident hostility that the French have shown to their great ecclesiastical monuments of the past. Not only have they either pulled them to pieces, or let them fall in ruins, but of what remains they have made such use as deliberately to throw discredit on them. The Cluny, and Bee, both mentioned in the *Anglo-Saxon Chronicle*, the latter the Abbey that produced the first two archbishops of Canterbury, Lanfranc and Anselm, are now stud-farms; Fontevrault, Clairvaux

and Cîteaux, penitentiaries,—and so on. Anyone who has travelled in England, and recalls Tintern, Farness, or Fountains Abbey, than which there is certainly nothing more completely beautiful in Europe, whatever the Orient may have to show, is simply horrified to see the fate that has befallen the great French abbeys. Cluny is a quiet, picturesque *ville de province*, in a smiling, very fertile valley near Mâcon; and its shady streets and arched walks are the frequentation of countless soldiers convalescing from less important wounds not requiring special attendance or first-class surgical skill. This is now the case all over France.

But the following evening we were away out of the busy world in a tiny hamlet of a remote Savoyard valley at the only inn the place afforded, though it was very comfortable. Here the scene was the same as everywhere in France, everyone's menfolk at the war, and the women, children and elders "carrying on." It is a remarkable sight to see fields, meadows, orchards, vineyards and livestock,—everything cared for just as usual, with all the able-bodied gone! Anyone who is anxious really to concentrate on a worthy topic will find an ample field in the French women of 1914-1915. They all say that the only real pinch will come when the mowing has to be done, as that is heavy work for women; all the remainder they can gladly tackle, and the way the endless vineyards looked all through that invaluable stretch between Dijon and Beaune, in which are produced the finest wines of the earth, was a witness to what women can accomplish when their back is to the wall, and it is a ground-hog case. It is often said by the knowing that the women are the backbone of France. Personally I am so terribly pleased for the moment with the French soldier, that I find it hard to be fair to anything else; but certainly, what I saw of those women up in Savoy filled me with unbounded admiration. One of the most striking examples I met right in this little hamlet: at the end of five minutes she and I nearly fell on each other's necks! I went into a tiny shop, to get some local picture-cards. The dame at the counter saw I was a stranger, learned I was from Paris, and then of course at once, "What did I think about the war?" Henceforth that was the inevitable: "*Monsieur habite Paris? Que dit-on lâbas de cette guerre?*" and this is what she told me: Lost her husband some years ago, and remained with one only son, steady and satisfactory in all respects, with whom she carried on this business, and had been doing very well. Then came the war, and off he went to Alsace with the rest of the *Chasseurs alpins*, who originate in this district, among the mountaineers, guides, chamois-hunters, poachers, etc., fine shots, most of them, and runners on skis. They say that music softens the human heart; but I am afraid that the same cannot be advanced for war. This woman was evidently the best creature in the world, motherly, kind, everything that could be wished; yet this is the style in which she talked. Her worthy offspring had, it seems, right at the beginning of the war, ambushed a motor-car full of German officers on the frontier at a railroad crossing by letting down the bar, and had pumped the car full of lead as the driver necessarily came to halt, sending three of the foes to the next world and bringing in the other two prisoners. "Où, Monsieur," said the proud mother, with tears of joy in her eyes, "il en a descendu trois à lui tout seul, et les deux autres se sont rendus; ensuite il a été félicité par son capitaine devant toute sa compagnie!" Soon after that he had some fingers shot off, but resumed his place in the ranks as quickly as possible. Finally, however, a big shell lifted him into the air with some tons of earth, and as he came down he ruptured himself, damaging a knee badly at the same time, something with the knee-cap, I gathered. And now the fond mother's main anxiety was to know whether I thought he had been sufficiently knocked to pieces to warrant an honorable discharge and his return to the parental hearth?

Up at the remote village where we finally settled down it was the same thing—all the husbands and brothers at the front, but happily but few men killed so far. The inn was run by an old couple, with the help of a daughter. This daughter's husband disappeared before Arras in October last, and has not been heard of since. All they know is that he has not been reported killed. Now as men are constantly being found after a silence of six, eight or ten months, this good woman still hopes on, although I fear that her chances are slight. She has four little ones, the last born soon after her husband left for the front. In that small group of houses on our side of the rushing mountain torrent there were no less than seventeen small brats with their fathers off at the war, and a mighty lively crowd of huskies they were, I can tell you, when school-hours were over and the band of them issued forth to seek what it could devour!

One of the most interesting types I met up there was a man I took as guide, a sergeant of *Chasseurs*, home on convalescent leave after an illness. This man was a professional poacher of chamois, quite a superior character, and his tales about stalking Germans in the winter forests of the Vosges were most thrilling. It seems that he is a known shot, at home, but there was no bragging about his stories; in fact, it was quite apparent that he had horror of killing a fellow-being, and was not very keen to speak about it. Yet by reading between the lines you could see that whenever there had been a particularly tough job on hand in his trench, he had been the marksman told off for it, and that he had generally accomplished what had been expected of him, for he followed up his, "*J'en ai descendu quelques-uns*," with a significant look that spoke volumes. He had one tale about suddenly and unexpectedly coming across a huge German when out as *chasseur* in the forest, and of jerking the butt of his rifle to his shoulder and instantly firing, that was most palpitating. As he said: "At moments such as that you must not lose time in thinking; if you don't get your man, *he gets you*,—that is all there is to it." The solution he proposed for the war was—at least so far as his corps of *Chasseurs alpins* was concerned, original, if nothing else. He said: "We are nearly all good shots, and afraid of nothing. If they would let each *chasseur* free from military service, and authorize him to go home, as soon as he had brought down five Germans, it would not be long before the entire battalion would be back here again among the mountains!" We went up a fine peak together one day, in such perfect weather as I have rarely seen, and had the view of a life-time; the entire chain of the Alps, from Chamonix, all along the Valais giants (with the Overland behind them), Savoy, Cogne, the Dauphiné, clear to Monte Viso without a cloud; it was a marvellous panorama. Now as we sat up there, eating a hasty lunch, thinking of the beastly 500-metre ice slope we had to get down again before the sun grew hot enough to make the laboriously-cut steps unsafe, what do you suppose my guide remarked, with an infinite depth of feeling? Every climber knows the almost uncanny stillness that reigns on the point of a sharp peak, no matter how much wind there has been on the way up; well, here is what he said: "At least you cannot hear the cannon up here!" He was one of the very few guides I have come with who really loved the mountains. It was fairly pathetic to hear him speak of how in two or three weeks he should again have to tear himself away from all that was dear to him, and return to the trenches; he seemed to have an absolute horror of the sound of cannon, in particular, and was constantly referring to it. He was married, with two small infants, and had just finished a house in which he had proposed to take on summer-boarders, when all his hopes were knocked on the head by the outbreak of war. I thought his passion for hunting would be the end of us, before the day was over, since instead of looking after the rope, and keeping an eye on his charge, he was everlastingly searching around for chamois with

a spy-glass. At our feet, when we were at the top of the mountain, lay spread out the entire district of Cogne, where the king of Italy has an immense preserve of chamois and bouquetins. I thought I was entertaining Jean with an account of this game, of how fearless it is, of how the cliffs over there simply swarm with it, and how a family of bouquetins neatly finished off my party one day by sending down a shower of stones on us; but apparently I had made a *faux-pas* somewhere—the guide looked neither interested nor pleased! Finally I ascertained that he and some friends on a certain occasion had crossed the frontier stealthily one night to do some judicious weeding out of the King's herds at early dawn, but had been caught by the *gardes-chasse*, heavily fined, and promised a spell of prison for the following offense!

Good old Jean! I don't know when I have warmed up to a public malefactor as I did to him. He was simply a splendid chap! And when this dreadful war is over, and this vast ocean of misery has had time to subside a little, I shall not fail to find out whether or not Jean has come through the conflict all right? If, as I hope, he does, I propose to go down there and stay with him a bit; and when I do, I shall be provided with the wherewithal to give him and his family the time of their lives. It is remarkable to note how all these men who have been through the fiery ordeal, and have experienced the real thing, think alike on the subject and on the future outlook: a quiet fatalism, as to their chance of life; but an absolute certainty as to the ultimate result: "Oui, c'est long; mais on les aura." This is the alpha and omega of their philosophy.

"S."

AN AMERICAN SURGEON IN ITALY AND AUSTRIA-HUNGARY.

(From Our Special Correspondent.)

AMERICAN RED CROSS MISSION,
K. U. K. RESERVE SPITAL NR. 4.

60, MEXIKOI-UT VII., BUDAPEST, July 26, 1915.

Mr. Editor: Doubtless one might find a more propitious time for travel, but the novelty of being on a ship belonging to one of the belligerents, having more "bundles" than would be healthy, even in normal times, adds spice to the adventure that in all probability is never to be duplicated. We had so much cargo that half of the water tanks had to be emptied, so as to keep the water line showing. The weather was very rough, and the wind high, on account of storms that persisted in following us, in spite of full speed and varying the changes of direction. The course was not plotted out for reasons best known to the commander—this added much to the thrill of the trip—but I venture to say it would have been very interesting to note the additional leagues sacrificed for safety. However, by the time we reached the Azores, we were caught between two heavy storms. These prevented us from landing, and a whole twenty-four hours was lost in sailing back and forth along the island, until finally the wind became so high that we were forced to put out to sea. The next noon we were able to get on to the lee side of the island and run into a little cove, and land our passengers by means of small boats, a thing that has not been done for months and months. However, "it's an ill wind"—as the saying goes. The sight of land had a very pleasing effect on those afflicted with "*mal de mer*," and the warm sun and the aroma from the variegated green fields, together with the calm sea, was better than all the "dope" ever written about in the *Pharmacopæias*. From what I could see of those islands, with their little Dutch windmills, I think I should like to spend a few months there. It is interesting to note that, although it rains nearly every day, there are

BUDAPEST: DIE FISCHERRASTEI MIT MATHIAS-KIRCHE.

always parts of the islands where one can enjoy fair weather, and as they are a matter of only a few miles in breadth, it is a very easy matter to drive into these places.

Our delay at the Azores made a difference of about thirty-six hours in getting to "Gib," where we found nasty rainy weather, which had been the program for the past ten days or so. Here we were closely examined for contraband goods. The ship anchored long enough only to discharge the Harvard Unit and a few passengers and to replenish our much-needed water supply. Only British subjects were allowed on shore. Therefore, we missed a *gory(?)* bull fight. On leaving "Gib" we ran into balmy weather, and on that evening enjoyed our first Italian sunset. The weather remained warm and clear for the remainder of our trip and the sea calm. Also, there was a remarkable change in every one as soon as we reached the Mediterranean. It seemed as if a great load had been lifted off us—we had a feeling of *safety*. On our way across the Atlantic we had to be very cautious; sail cloth was lashed over the decks and state-room windows, also over the skylights of the saloons at night, and the life boats were in constant readiness for any emergency that could possibly arise. The whistle blew only at noon, in spite of the frequent fogs; the wireless was not in use except to "switch" the Associated Press news at mid-night, so you see we had one of those experiences that you read about in the "*best-sellers*." All the above changed when we entered the Mediterranean—we felt *free* once more.

On our way to Naples the monotony was broken by the passing of several French and Italian cruisers, and also many, many trawlers bound for the Dardanelles. The evening before we reached Naples we could smell distinctly the odor from Vesuvius.

The day we entered Naples was a beautiful, balmy spring day, clear as a crystal, which showed off its harbor to the best advantage, but I had either too high an idea of it from reading, or else I am no connoisseur of Nature. I was a trifle disappointed, for I could not but think that the Portland harbor was a much prettier one than that of historic Naples. Of course the old sentinel Vesuvius was grand and austere, with his halo of sulphur di-oxid.

As we neared the dock we were greeted as usual by the classical parasites for which, plus the squalor, Naples is noted. We had great sport watching these little beggars diving for money, and listening to the Neapolitan musicians. Just to show you the feeling of the people at that time, one of the ladies on deck threw a Krone in the water. The little urchin refused to dive for it, and instead showed his disdain for the K. U. K., by putting his thumb to his nose and extending his fingers. Thus you will understand why I issued orders to the party not to speak German while on Italian soil. As the boat was not to sail for over twenty-four hours, we had a chance to see some of Naples. First we hired an auto and went to Pompili, having lunch at the Hotel de Suisse, which is at the

K. U. K. RESERVE SPITAL NO. 4. A. A. R. C.

entrance to the reservation. After giving it a thorough inspection we started back. The scenery was beautiful. We were much interested in seeing the spaghetti shops and most of all, to the amusement of our guide, the way they deliver the milk (either cows' or goats'). It is delivered to the door, absolutely fresh and warm, and it is the only way you can be sure that the product comes directly from the producer to the consumer. We had opportunity to see another interesting custom, as you may remember, it was the Wednesday before Easter that we were in Italy, Naples, to be exact, and on this day the farmers bring in lambs and sell them on the streets. These lambs are killed for the Easter Sunday dinner, and it is very interesting to see the children leading a little lamb home.

After we had bought the usual things that every one does in Naples, viz. gloves, we had a real Neapolitan dinner. The next day we took the same guide and visited the important churches, and Museum, getting back to the boat just in time to get on board. Our trip to Genoa was uneventful except for a most glorious moon.

We arrived in Genoa on Good Friday A.M., but owing to delay it was not till after lunch that we could go ashore. Oh! what a difference. Genoa and Genoa stand for the things that Naples does not, viz.: no beggars, clean streets, thrifty business and industry, and education. This birthplace of Columbus prides itself on being like an American city. We visited the principal points of interest here, including the world renowned Campo Santo, the description of which is beyond words.

We were unfortunate enough to stop off at Milan long enough only to lunch and see the wonderful historic cathedral and see a few of the principal streets, as we wished to spend Easter in Venice. Suffice it to say that Milan is a real metropolis and I imagine worthy of quite a protracted visit.

Inasmuch as there were very limited train service and also accommodations, no sleepers was the main complaint,—we decided, not unwisely, to spend Easter as a holiday in Venice (the construction of this sentence is very poor) and now that things are as they are I am not at all regretful. We went to high mass in St. Mark's in the morning and also fed the pigeons on the Piazzetta, and, after we had had lunch, instead of taking a steamer, we took a gondola, and were sculled over to Lido, the Coney Isle of Venice. Here we had a very enjoyable afternoon watching the people promenading, engaging in all sorts of amusements, and we partook of our "suzsonna kark," which is Hungarian for Jause, on a veranda overlooking the Adriatic, watching the people in bathing. In the evening we took another gondola and saw Venice by moonlight, a truly wonderful spectacle. One of these days, if Venice is still on the map, I want to see one of its carnivals.

In order to get to Wien we had to leave Venice at the ungodly hour of five A.M., but when the weather is mild, and when there are new sights to see, one does not mind early rising. It is the most delightful trip from Venice to Wien—words will not in any way describe it. The mountains, the valleys, the newly-planted fields, the villages and all, one would have to be a novelist of the first water to attempt to give even the faintest idea of the route. Throughout the country everyone we came in contact with treated us with great pains, but we could not but help noticing that we were under a very careful chaperonage, and as we approached the frontier, it became more and more evident. On the train to Pontebba we were under strict surveillance by a plain-clothes man who was relieved at every stop. It was very easy to see that the country was mobilizing, for we literally stumbled over men in uniform everywhere, and on the train there were hundreds of men being put off at every station on the way towards Pontebba. We could see the guards and trenches and batteries from the windows. Everyone we saw had an air of business and secrecy tending almost to furtiveness, and if we could have got them to talk we would have had no end of news.

Upon reaching the border, things were more agreeable; it seemed as if everyone could not do enough for us.

I will not bore you with any more of my experiences. Suffice it to say that I am here in a beautiful city and pleasantly located. I have not had time to get around to the clinics, as my mornings are taken up with this work, but I long for some surgical work.

Sincerely yours,

RICHARD METCALF, M.D.

AN AMERICAN SURGEON IN FRANCE.

(From Our Special Correspondent.)

PARIS, AUGUST 4, 1915.

Mr. Editor: One need not be in France many hours before realizing that it is indeed a nation at war. Crossing, as I did, upon a French boat, that fact became fairly well established even before we sighted the shadowy hills of "la belle France." Of the not very numerous passengers, at least half were intimately connected with the war. Several of the men were coming to enlist. One of them, chef in a New York hotel and a naturalized American citizen, explained to me that he would have to work for the rest of his life alongside of men who would talk of nothing but the war. If he did not enlist, he would be compelled to be silent for the remainder of his days. There is much philosophy in his words.

Of the women, one had lost a husband in the war, and, travelling with her little boy of three, she was going to find his body and remove it to the family plot. Another was crossing to join her husband who had been injured in the service. A third told me she had five brothers and nine cousins at the front, and that she had not heard from her relatives at Lille for almost a year. It is surprising how cheerful people can be under such circumstances, but the French are optimistic and great believers in Destiny. "Why worry about submarines?" said one to me. "If we are to die that way, we shall not be hanzed." He was right not to worry, for, aside from the alarm caused by several spar buoys at the entrance to the River Gironne, which were thought by the uninitiated to be periscopes, our crossing was free from any suggestion of naval warfare.

We landed at Bordeaux in the teeth of the military authorities. An entire tribunal sat upon our passports, so to speak. The court was presided over by an elderly French officer in uniform, with several dec-

orations on his chest, and a most genial and quizzical expression.

Bordeaux was full of soldiers, some in the old red-trousered uniforms of Napoleonic fame, much the worse for wear; others in the neat bluish-grey uniform of the most recent vintage. The station was full of them; every train carried them away. To witness their leave-taking is to comprehend to some degree the real meaning of war to the enlisted man, and even more to his family.

The women seem brave; the majority are in mourning, but it is distinctly French mourning, with a certain dash which seems to lighten the sorrowful side.

At every station soldiers boarded the train. For the most part they looked like earnest, strong men in whom one felt instinctive confidence. Ladies collecting for the Red Cross passed through the train at every stop. It seemed as though at least three quarters of the people of France were directly interested in the war. The fields, nevertheless, are well cared for. It is harvest time; the wheat is being gathered.

We reached Paris after dark. It is indeed unusual to see a great city carrying on its activities under cover of darkness. Jangling cabs emerge from dark streets; taxicabs dash upon the unwary one from the gloom.

I attempted a stroll, but was shortly collared by a huge, boisterous French infantry man who was "illuminated" somewhat more than were his surroundings. He insisted upon our having a glass together, which we did. We must have been a queer pair, but nothing seems to attract attention nowadays.

He was to leave for the Dardanelles, he said. For just a year and a day he had been mobilized, and although he illustrated by eloquent gestures just what he would do to the Turks, one felt him to be a mere fool, unintelligent and not understanding, in the great machinery of war. He was a farmer, he said; he had a wife and three children. He was gaunt, clumsy, thick of speech; he would accept nothing but one glass of wine with "a comrade."

Before very long I shall hope to be able to write you a letter more from a medical point of view.

Yours very sincerely,

G. G. S.

BLOODLETTING IN HEART DISEASE.

WESTPORT, N. Y., September 9, 1915.

Mr. Editor: In reading the discussion of the papers on heart disease, in a recent issue of your JOURNAL, I was very glad that physicians of highest reputation, like Drs. Shattuck and Christian, spoke strongly in favor of venesection in certain cases of cardiac disorder. I shall hope that their voices will not be ignored at the present time. Too often I see instances when I am confident life is shortened or lost by the unwillingness of physicians to use the lancet and thus aid markedly and rapidly a struggling and over-taxed heart. If venesection is objected to, the application of a few leeches to the precordial region, will do wonders at times. Sad to write, however, it is today, difficult to obtain leeches. Even in our large city pharmacies, they cannot be purchased because they are not kept in stock. It is among only a few German druggists, like Elmer and Amend, of New York City, that they are constantly kept on hand. Not long ago, I had this practical experience, and although I obtained the leeches for the patient I saw in consultation, consent was not given to the family physician to apply them. In the over-distended heart of pneumonia, particularly where the right heart is acutely enlarged and the jugular veins are largely increased in size and pulsating visibly, while the lips and fingers are cyanosed and every breath is a labor and torment, heart stimulants are absolutely worthless unless there be bloodletting freely, either by venesection, or locally with leeches. There is no need, in

my judgment, to follow it with a saline infusion. Even in instances where, perhaps, too much blood has been taken, the danger to the patient is increased, rather than diminished by this means. I much prefer a rectal injection of salt and water with some black coffee, if required.

More than once, I have seen a patient, as I believe, die from the use of salt solution by the vein after seemingly, a successful venesection. A most regrettable fact connected with modern, advanced scientific treatment, is the abandonment of a method usually, which properly practised, is of great value to many sufferers.

In times of great stress and imminence, the now somewhat "lost art" of bloodletting, as Dr. Samuel D. Gross, that great American surgeon had it, is unequalled in its power for good.

BEVERLEY ROBINSON, M.D.

BELGIAN PHYSICIANS' RELIEF FUND.

REPORT OF THE TREASURER OF THE COMMITTEE OF AMERICAN PHYSICIANS FOR THE AID OF THE BELGIAN PROFESSION FOR THE WEEK ENDING SEPT. 4, 1915.

No contributions for the week ending Sept. 4, 1915.

Previously reported receipts.....\$7814.84

Total receipts.....\$7814.84

Previously reported disbursements:

RECENT DEATH.

DR. SAMUEL W. DANA, who died on September 1 in New York City, was born at West Lebanon, N. Y., in 1827. After obtaining his preliminary education at the Kimball Union Academy he received the degree of A.B. from Dartmouth College in 1854, and that of M.D. in 1858 from the New York College of Physicians and Surgeons. Upon graduation he immediately settled in New York where he continued active in the practise of his profession until his retirement in 1908. He was a member of the New York Academy of Medicine, the New York County Medical Society and many other organizations. He is survived by two daughters and one son.

APPOINTMENT.

Dr. J. A. Menzies has been appointed professor of physiology at the Medical School of the University of Durham, Newcastle-on-Tyne.

I.

LOCALIZING NEEDLE FRAGMENTS IN THE TISSUES OF THE BODY BY MEANS OF MAGNETISM. DEMONSTRATION.*

BY GEORGE H. MONKS, M.D., BOSTON.

DR. MONKS called attention to the fact that in certain cases in which needles, or needle fragments, are buried in the tissues of the body, the use of magnetism may help the surgeon in localizing the foreign body. In order to use the magnetic test it is necessary first to magnetize the buried needle, and then, by means of a delicate magnetized indicator of some kind, to localize it.

To magnetize a buried needle an ordinary steel magnet usually suffices, and for an indicator a fine magnetized needle suspended at, or near, its middle by a fine silk thread or even by a human hair. A very small compass may also be used.

The magnetic test is apparently only applicable in those cases where the buried fragment is large, and near the skin.

The technic of the method was then demon-

strated, and a box containing a number of needle-fragments which had been localized by magnetism, and removed from patients, was passed about for inspection. Accompanying this box were fine magnetized needles attached to delicate silk threads, for use in applying the magnetic test to the needle fragments in the box.

DISCUSSION.

DR. W. M. BOOTHBY, Boston: The apparatus devised by Dr. Monks is excellent for locating small elongated bodies, like needles, lying only a short distance below the skin.

It may be of interest to bring to your attention an apparatus recently devised by Prof. Bergonie of Bordeaux for locating fragments of shrapnel imbedded in the deeper tissues. While we were at the American Ambulance Hospital, Paris, Prof. Bergonie demonstrated the apparatus to the Harvard Unit. The apparatus consisted of an electric magnet of considerable power and a motor for rapidly reversing the direction of the electric current. When the electricity flowed in one direction the magnet would attract; when flowing in the opposite direction it would repel the steel or iron fragment. The rapid reversal of the magnetic force set the foreign body into vibration and the palpating finger of the surgeon could locate the body as being directly beneath the point of maximum vibration. By using a sterilized point the exact location could be reascertained after the incision was made and the surgeon was working in the approximate region of the shrapnel fragment.

II.

ACUTE PERFORATION OF ULCERS OF THE STOMACH AND DUODENUM.*

By IRVING J. WALKER, M.D., BOSTON.

THE stomach and duodenum are today receiving more attention from a surgical standpoint than any other of the viscera. We have now so perfected the diagnosis and the surgical technic of the operation for chronic ulcer of these organs that the mortality from operation is comparatively low. For the time being, in this enthusiasm, we have overlooked the disaster that may result from harboring a chronic ulcer, namely, acute perforation of the stomach and duodenum. There is no condition in which the picture of apparent health is so suddenly changed to one of gravity, so eminently fatal if not recognized early, and so amenable to treatment if operated on without loss of time.

The cases upon which this paper is based were gathered from the surgical records of the Boston City Hospital for the years 1905 to 1914, inclusive. Interest in the subject was aroused by the somewhat high mortality generally attributed to this lesion, in the hope that some reason might be found accounting for this. The series covers 78 cases, operated upon by 17 surgeons. With so large a number of operators, one would expect to find a greater or less variation in operative procedures and end results. However, this was not the case. The technic was, in general, similar, and the operative results practically the same. Nevertheless, a few conclusions have been derived from the review.

Etiology. As to the cause of perforation of the stomach and duodenum, no new light has been cast by this study of 78 cases. Males were found to have been affected more frequently than females, in the proportion of 12 to 1. The average age of the males was 35, and of the females, 29. Sixty-six and two-thirds per cent. gave a definite alcoholic history. Probably few of the others were abstainers, judging from the trend of cases admitted to such an institution. While alcohol, perhaps, played no part in causing the perforation, we certainly can indirectly attribute to it a considerable percentage of the mortality, as of those who succumbed 78% used alcohol in more than moderation. This factor and the lack of nutrition in many of the individuals undoubtedly makes the mortality higher in such cases in the large hospitals than we find in private practice; and for this reason one should not compare the statistics of the two.

The site of the perforation was found to have been in the stomach in 42 cases, and in the duodenum in 36 cases. The perforations of the stomach were invariably located within one and one-half inches of the pylorus. In all except two, the site was on the anterior wall, and generally nearer the lesser curvature. The perfo-

rations of the duodenum were all found upon the anterior wall except one. Although Eliot¹ collected eighteen cases in which there had been multiplicity of perforations, none were found in this review. Nevertheless, one should be on constant guard lest a second perforation be overlooked,—as were most of those described by Eliot, being discovered only at subsequent autopsy. Especially is this true of the perforations on the posterior wall of the stomach, which can be easily overlooked unless gas, stomach contents, or exudate appears in the lesser peritoneal cavity.

Diagnosis. In the diagnosis certain symptoms and signs stood out above all others found in the condition, and should be more fully explained. As one might expect, nearly every case gave a previous history of a lesion of the stomach or duodenum which had lasted from a few weeks to several years. The symptom of perforation that was most prominent was the character and location of the pain. This was invariably described as sudden, severe, and sharp, localized generally in the epigastrium, radiating at times into the right lower quadrant. In not a few cases, this sudden onset had been preceded for several days by more or less indefinite pain located in the region of the epigastrium, terminating in the sudden, severe type described above. Many times vomiting immediately followed this severe attack of pain, but was not persistent unless peritonitis was present. Occasionally it was observed as being prolonged before peritonitis had developed in cases of duodenal perforation. This has been described as due to the fact that in perforation of the stomach, with even slight expulsive effort, gastric contents escape more easily through the perforation into the peritoneal cavity than upwards through the esophagus; while in perforation of the duodenum, the stomach is intact and the mechanism of vomiting therefore undisturbed. The classical symptoms of peritonitis seen in most of the fatal cases need not be described.

Shock has been cited as a most important symptom of perforation. In reviewing this series, however, the writer was impressed by its absence in the majority of cases. Examination of the records shows that shock when present is more frequent in perforation of the stomach than of the duodenum. We have no explanation for this observation. Certainly, the amount of shock seen in perforation cannot approach in severity that found in acute pancreatitis or mesenteric thrombosis. Absence of liver dulness, so often spoken of as a sign of perforation, was recorded only five times. Whether this sign was not present or was not discovered cannot absolutely be determined. Suffice it to say, the impression that it made upon the minds of those examining the cases was not great enough to incorporate its presence or absence in the records. Therefore, we are led to believe that the value of this sign in the diagnosis has been exaggerated. Shifting dulness in the flanks, showing

* Read before the Section of Surgery of The Massachusetts Medical Society, June 8, 1915.

fluid, was found in 18 cases. In a board-like abdomen, its presence can be of value in making the diagnosis of perforation only when taken in conjunction with the other symptoms and signs.

Differential Diagnosis. The most common condition with which perforation of the stomach and duodenum has been confused is acute appendicitis. This mistaken diagnosis occurred seven times in this series. The reason is easy to see. In acute perforation, pain may be referred to the region of the right lower quadrant of the abdomen because of the fact that the contents of the stomach or duodenum have gravitated in that direction, producing peritoneal irritation in that region. However, in acute perforation, tenderness and spasm are most marked in the epigastrium, and in acute appendicitis in the right lower quadrant. As peritonitis progresses, the difficulty of differentiating these conditions increases, and often the diagnosis cannot be made until operation.

Acute disease of the gall-bladder or pancreas may simulate perforation. The close relationship between the duodenum and the gall-bladder makes it evident how lesions of the one may resemble those of the other. In both, the tenderness and spasm is most marked in the epigastrium, but in perforation it is more apt to be localized nearer the median line. Fluid, if present, is much less in amount in acute disease of the gall-bladder than in perforation. From the location behind the stomach and duodenum, one can easily perceive how acute disease of the pancreas can resemble perforation. However, the degree of shock in acute pancreatitis is more severe than is generally seen in perforation; but here again, as in acute appendicitis, the diagnosis can frequently be made only when the peritoneal cavity is opened. Happily for the surgeon, perforation, acute pancreatitis, and acute disease of the gall-bladder, can usually be treated through a similar incision: one to the right of the median line between the lower border of the ribs and umbilicus. As to differentiating between perforation of the stomach and perforation of the duodenum, while an interesting point in diagnosis, is perhaps not absolutely necessary as it would not influence surgical treatment in case of operation.

Treatment. The treatment of acute perforation of the stomach and duodenum is unquestionably surgical once the diagnosis has been made and the patient in condition to stand operation. Observation, in such cases, results only in a higher mortality. One procedure that all surgeons agree upon is the necessity of closure of the perforation by some means. Suture is the ideal way of closing the orifice. However, instances arise when this is impossible because of the inaccessibility of the opening, or the friability of the tissues to be sutured. Bessel-Hagen² and Downes³ have utilized the gall-bladder as a means of closing the perforation. Others have used flaps of omentum to suture the orifice. Still others, as a last resort, have simply tamponed

the openings with gauze. Cases treated in this way may recover, but usually present a fistula, which may or may not close spontaneously. The question of how much more one should do in the way of operative measures is not yet settled. Theoretically, we should all like to excise or enfold the ulcer-bearing area and do a gastroenterostomy in every case. Practically, however, this is not always feasible, owing to the condition of the patient or to the danger of spreading the already existing infection. Gastroenterostomy becomes a necessity in any case where the pylorus is greatly narrowed because of suture of the perforation. It becomes a matter of choice in the small group of cases seen soon after perforation, where the infection is local and the patient is in good condition. In this group, most writers agree that the procedure is safe and well worth while as a curative measure for the existing ulcer. However, it is not a necessity, as it is well known that the vast majority of perforated ulcers heal with suture alone without gastroenterostomy. In this series, gastroenterostomy followed suture of the perforation in three cases, with recovery in each instance. Given a patient of good operative risk seen immediately after perforation, one would not hesitate to enfold the ulcer and do a gastroenterostomy. However, the average operator will have a lower mortality in a large series of cases by simply suturing the perforation and later, if judgment warrants, doing a gastroenterostomy with comparative safety.

The question of irrigation of the peritoneal cavity was interesting to the writer. In this series, the cavity was generally irrigated in 20 cases, with 9 deaths and 11 recoveries. All the cases irrigated showed a peritonitis more or less marked. Therefore, one should consider a similar variety of cases not irrigated. Of those cases showing peritonitis, which were not irrigated, there were 9, with 5 deaths. The figures here given tend to show that general irrigation of the peritoneal cavity was beneficial in cases of diffuse peritonitis. In the others, it is probably far better to do the cleansing with wet sponges.

It has been said that drainage is not necessary in those cases seen soon after perforation, since the contents of the stomach and duodenum are usually sterile and what infection there is will be cared for by the peritoneum. In 29 cases in this series, cultures were taken from the fluid in the peritoneal cavity. Of these, 14 showed bacterial growth, and 15 were negative. There can be no way of determining macroscopically in a given case whether the fluid present is sterile or not, and if not sterile what may be the number and virulence of the organisms. It was undoubtedly good judgment that led the operators in this series to drain in all except two cases. However, there are cases seen immediately after perforation, where the escaped contents, if not large in amount, can be sponged out and the abdomen closed without drainage. In most cases

where fluid was found in the pelvis, that part of the abdomen was drained through a stab wound. The drains were all dispensed with in from two to four days, unless secondary abscesses developed.

Complications. The most common complication found was peritonitis. This was given as the cause of death in 14 of the 21 cases.

Occasionally it resulted in a localized abscess in the pelvis, right lower quadrant, or subphrenic region.

Post-operative hemorrhage and shock were given as the cause of death in three instances. Pneumonia occurred six times, with four deaths.

The other complications recorded were pleurisy with effusion, and abscess of the lung, with recovery in each case.

Results. In the above series of cases, there were 57 recoveries and 21 deaths, a mortality of 26.9%. This is considerably lower than the mortality usually attributed to this condition. As we have stated above, the individuals were, for the most part, poor operative risks. Add to this the fact that the average duration of the perforation was 25.9 hours. Of those who recovered, the average duration of the perforation was 14.5 hours, and of those who died 37.3 hours. Seventeen were operated upon during the first four hours, and all recovered. Of those operated upon from 5 to 12 hours after perforation, the mortality was 17.9%; of those operated on from 13 to 24 hours, 47.6%; and of those from 25 to 48 hours, 66.2%. Ten were operated upon after 48 hours, with 5 deaths and 5 recoveries. Of those who recovered, it should be said that each had a walled-off abscess, and not a generalized peritonitis, thus accounting for the recoveries.

It would appear from the analysis of these cases, as well as from those of other writers, that a high mortality can generally be attributed, not to the technic of operation, but rather to the unpardonable mistake of allowing such cases to wait hours before surgical advice is sought. A certain number of patients are themselves responsible for the error of not having sought in time medical advice for chronic ulcer of the stomach and duodenum, and later for the symptoms of acute perforation. However, a goodly number of others are themselves blameless, having been rather indifferently treated for indigestion, stomach trouble, or even ulcer, without having the importance of following up the treatment and the danger of the existing lesion impressed upon them.

CONCLUSIONS.

1. The history of disturbance of the stomach or duodenum should always be sought for in cases of suspected perforation.

2. Sudden, severe epigastric pain is the most constant symptom in the diagnosis of this condition.

3. Shock is an inconstant symptom.

4. The value of the absence of liver dullness as a sign of perforation of the stomach or duodenum has probably been overestimated.

5. Simple closure of the perforation, with drainage of the peritoneal cavity is the safest procedure in the majority of cases.

6. The mortality can be diminished by greater care in the diagnosis and in the treatment of chronic lesions referable to the stomach and duodenum, so that but few are allowed to reach the stage of perforation, and even those, given the benefit of surgical measures while the chances of recovery from operation are still good.

CONCERNING TRAUMATIC RUPTURE OF THE DUODENUM AND DUODENAL FISTULA. WITH THE REPORT OF A CASE.*

BY DAVID CHEEVER, M.D., BOSTON.

[From the Peter Bent Brigham Hospital, Boston.]

1. The comparative rarity of rupture of the duodenum, due to injury, and more particularly of cases of recovery from this condition, justify the reporting of a single case and a discussion of the principles involved in its treatment, which are not confined in their application to this particular trouble.

The patient, R. J. S., a schoolboy fifteen years of age, on January 6, 1914, tried to cross the street in front of a slowly moving automobile, but slipped on the ice and fell down in front of it. Witnesses stated that one front wheel ran over his body. The accident occurred at 1.30 p.m. He was able to extricate himself from under the car, and walk to the sidewalk, whence he was taken home, and his physician called, who found him in a condition of shock and suffering a good deal of abdominal pain. He was brought to the Peter Bent Brigham Hospital, about one and a half hours after the injury.

Examination showed a well developed boy in a condition of slight shock; pulse 50, blood pressure 110, respiration somewhat rapid, temperature normal. Except for a slight abrasion on the left thigh, there was no external sign of injury. The abdomen was slightly tender and spastic generally, but there were no localizing signs, and, with the exception of slight dullness in either flank, which did not change on change of position, was practically negative. At this time the points of maximum tenderness were on either side about the level of the umbilicus. The objective signs did not seem to justify intervention at this time, especially as the testimony of witnesses differed as to whether or not the boy had actually been run over or simply thrown to the ground and stunned. When seen again, about three hours later, he looked more sick, had begun to complain of abdominal pain, and showed fairly well-marked

* Read before the Section of Surgery of The Massachusetts Medical Society, June 8, 1915.

tenderness in the right iliac region.—scarcely any tenderness in the epigastric region. During examination at this time the patient vomited a small amount for the first time. Pulse was 84. Diagnosis of probable rupture of a viscus was made. An operation was advised, and later accepted.

About eight hours after the original injury, under ether anesthesia, the abdomen was opened in the middle line below the umbilicus, since the evidence seemed to point more to an injury in the lower abdomen than elsewhere, and in the writer's experience the lower part of the ileum had been the most frequent seat of traumatic rupture. Free gas and a large amount of bloody, brownish fluid was found, and sponged out of the pelvis and either iliac fossa. The small intestine was now examined from the ileo-cecal valve without finding any injury. It was not until a sponge was thrust upward toward the region of the gall-bladder that the first correct clew as to the seat of the lesion was found in the appearance of a green staining, evidently due to bile. Another incision was at once made through the right rectus from the costal border downward, and, after considerable difficulty, due to the infiltration of all omental tissues by the extravasating fluid, a laceration admitting a thumb was found on the posterior aspect of the first part of the duodenum about 3 cm. distal to the pylorus. It was circumferential to the long axis of the gut, and its edges were pointing as though it had been caused by a bursting force. Its situation was such that it was in part extra- and in part intra-peritoneal, which made closure difficult, but a fairly good repair was made with chromic cat-gut. The abdomen, all of which showed traces of extravasated fluid, was thoroughly washed out with salt solution, and drains carried down to the injured duodenum and to the bottom of the pelvis. The patient left the table in rather poor condition.

The immediate after-treatment consisted of the Fowler position, proctoclysis, and appropriate stimulation. For the first three days, he showed marked toxemia and seemed to be going down hill, but then began to improve. On the fifth day after the operation, a suspicious discharge appeared in the upper wound, together with evidence of tissue digestion and skin irritation. Soon after, a profuse, bile-stained, extremely irritating discharge became established, which caused the wound to re-open throughout its length, undermining the skin and rapidly digesting the skin edges and the tissues of the abdominal wall. Whatever food was ingested appeared in a few minutes afterward in the discharge, and it seemed unlikely that any material portion passed onward. The boy's general condition was now very poor, showing more prostration and exhaustion than would be expected merely from the lack of nutrition and the amount of obvious infection, since there was no evidence of a general peritonitis. It was evident that, unless the discharge could be stopped, a fatal issue must come. Accordingly, a small rubber tube was carried down to the bottom of the wound, and held in place by appropriate means, and a continuous irrigation of the sinus with sterile water inaugurated,—the overflow being conducted into receptacles by means of a bank of rubber tissue, which was made to adhere to the skin about the wound by means of chloroform. By this means the digestive juices were kept highly diluted, and immediate cessation of the destructive process was noted, together with an improvement in the patient's general condition. This continuous

irrigation was continued for five days and nights, requiring the presence of an attendant constantly by the bedside. On the fifth day, it was omitted in part, because the secretion had markedly diminished, and no more food was appearing, and on the sixth day it was discontinued, and from that time there appeared no more leakage from the fistula, and the wound began to heal satisfactorily. No more trouble was experienced from this source, but the rest of the convalescence was stormy, requiring three subsequent laparotomies in the course of the next month for the drainage of large residual abscesses in the lesser peritoneal cavity, in the right iliac fossa, and in the pelvis, respectively.

He was finally discharged fifty-eight days after his admission, and has since made a complete convalescence, and presents no symptoms referable to this illness.

Ruptures of the intestines by trauma are relatively common lesions, and of these the duodenum, by virtue of its fixed position against the spine, yields its share. Berry and Giuseppe¹ analysis of 132 lacerations of the intestinal tract gives the following figures:—

Large intestine.....	10
Duodenum.....	23
Duodeno-jejunal flexure.....	3
Jejunum.....	32
Ileum.....	32
"Small intestine" (not further specified).....	25
Large and small intestine together.....	4
Incomplete rupture.....	3

Hertle's² figures in 122 cases are not essentially different:—

Large intestine.....	10
"Small intestine" (not further specified).....	31
Jejunum.....	29
Ileum.....	40
Duodenum.....	12

Combining these figures the conclusion is reached that 13.7% of all intestinal ruptures (excluding lacerations due to instrumental perforation of the abdominal wall) involve the duodenum, or nearly twice as many as involve the large intestine (7.8%).

Traumatic rupture, wherever localized in the intestinal tract, is notoriously fatal. Combining the figures of three large series of cases, those of Berry and Giuseppe, Hertle and Travast-jerna,³ we find a general mortality of over 80%. Yet even more striking are the figures for rupture of the duodenum, 92.6%; or, including 4 cases reported in the last year, 93.1%. Several obvious factors contribute to this mortality,—the largely retroperitoneal situation of the duodenum permits the rupture and extravasation to be extra-peritoneal where its evidence is masked until too late, or where it is actually overlooked during exploratory laparotomy. Thus Meerwein,⁴ writing in 1907, states that of 28 cases of extra-peritoneal rupture operated on, in six the lesion was not found until autopsy. The rapid and extensive diffusion of the infiltration is favored by the loose areolar tissues of the pos-

terior abdominal wall, so that huge phlegmons are frequent. The deep-seated and inaccessible tear presents technical difficulties in operative closure. Finally, the noxious character of the contents of the duodenum, whether merely intensely irritating and digestive in their action, or possessed of a specific toxic action, must be reckoned with.

In an interesting paper, Kanavel⁵ reports two cases of traumatic rupture of the duodenum, following the kick of a horse and a blow by a wagon pole, respectively, operated on 52 hours and 34 hours after the injury and presenting a rupture of the retro-peritoneal portion of the duodenum in each instance, and in addition, in the first case, a laceration of the root of the mesentery, which allowed the extravasation to enter the abdominal cavity. Both patients died,—one 6 hours and the other 50 hours after the operation; in both instances it seemed that death was more speedy and apparently the result of a much graver toxemia than would be expected from the degree of peritonitis, or of local injury, existing.

Reasoning from his observation of this peculiar toxemia, and from the well-known fatal course of high intestinal obstruction, both experimental and clinical, in which the secretions of the duodenum undoubtedly play an important rôle, Kanavel ascribes a specific toxicity to the extravasated material. In most of the recorded cases no especial stress is laid by writers upon this point. Sometimes, indeed, the fatal progress of the disease is comparatively slow, as in Maddock's⁶ patient, who was seen six weeks after a severe blow in the right abdomen, when an extensive subphrenic and retroperitoneal phlegmon was incised, followed by death in seven days. Autopsy showed a rupture of the second part of the duodenum. In comparatively few instances has fat necrosis been reported. On the whole, while a specific toxicity may well be suspected, it cannot yet with certainty be ascribed to the duodenal contents, in the absence of changes wrought by stasis and circulatory strangulation incident to obstruction of the gut. Kanavel reviews briefly the literature of this subject to date, including 94 cases which show a mortality with or without operation of 92.6%. Since his paper, a brief review of the literature discloses four additional cases, all operated on and all fatal.

The mechanism of traumatic rupture of the intestinal tract in general is usually described under three heads: a rupture due to (1) a crushing force, (2) a bursting force, and (3) a tear due to sudden traction. In the first group, the intestine must be compressed between the impacting force and a part of the skeleton, as the spinal column or the pelvis. Evidently the third portion of the duodenum, fixed across the lumbar spine, is ideally situated for this lesion, and it is in fact the part of the duodenum most frequently injured. Keller⁷ considers that the bursting rupture is very rare, since it is sup-

posed to require that the loop be full of liquid whose means of egress is obstructed, and since the duodenum is rarely full he believes that its traumatism are not of this character. To the writer, however, it seems probable that the present case belongs to this class, since the automobile wheel mounting upon the abdomen from the right side would naturally drive the gaseous and liquid contents of the second part of the duodenum against the closed pylorus, thus effectually producing a bursting pressure. Moreover, it is difficult to conceive how the first part of the duodenum, retreating from the convexity of the lumbar spine, could be subjected to a direct crushing force sufficient to produce rupture.

The symptomatology of this condition needs no extended comment. Local pain, muscle spasm, tenderness, increasing pulse rate, later vomiting, perhaps shifting dullness in the flanks, leucocytosis, unless the toxemia be overwhelming, constitute the familiar picture of a severe abdominal lesion. A word of warning may be uttered, however. If the rupture be retroperitoneal, the condition may at first be masked, but soon a tender tumor, not shifting, in the right hypochondrium and umbilical region, with evidence of physical shock will give the clue. If intra-peritoneal, the effusion may cause pain not so marked at the point of rupture as in the more dependent portions of the abdomen,—the iliac fossae or the pelvis, due apparently to the intense irritation of the peritoneum by the gravitated contents. In the present case this was the cause of an ill-placed primary incision and loss of time. Absence of liver dullness, a sign handed down from text-book to text-book as pathognomonic of rupture of a hollow viscus, is in reality a hollow mockery. Rarely demonstrable in the early and curable stages of a perforative peritonitis, when found it gives assurance of the correctness of the diagnosis and of the hopelessness of intervention.

When the abdomen has been opened and the lesion identified, what course shall be pursued? Repair of the rupture by suture, resection of the bruised bowel with gastro-jejunostomy and duodeno-jejunostomy, closure of the proximal limb and gastro-jejunostomy, leaving the duodenal contents to find their way through the pylorus and thus into the intestine, have all been successfully practised. It is no time, however, for elaborate procedures. The evidence is overwhelmingly in favor of promptness, simplicity and speed. A simple repair of the laceration by suture, washing out the extravasated material, and the institution of proper drainage are the indications, reserving resections and anastomoses for the rare cases where local repair is impossible. If the patient survives the immediate effects of trauma, the operation for repair of the lacerated bowel, the threat of peritonitis and of a primary retro-peritoneal cellulitis, a complication of gravest portent may be introduced by the failure of the repair and the establishment

of a duodenal fistula. Such a fistula never heals unaided, and if not healed is invariably fatal. Pannett,⁸ writing in 1914, reports a case of recovery from a duodenal fistula, and says but three other cases are to be found in the literature of the previous ten years, and indeed one of these, that of Berg, should scarcely be included, since, although a duodenal fistula following a cholecystenterostomy ceased discharging, the patient died 17 days after operation! W. J. Mayo,⁹ writing in 1914, reports 3 cases due to injury to the duodenum by a clamp placed on the kidney pedicle during a right nephrectomy, all fatal. Subsequently,¹⁰ in 1915, he reports an additional case where he exposed the laceration by transperitoneal mobilization of the duodenum and repaired it, with recovery. Probably further reports will show many recoveries from duodenal fistula, but of its gravity there can be no question. The methods of combating these fistulae are of vital interest to the surgeon confronted by one. The secretion evidently is composed of the gastric juice with whatever food has been taken, the bile, pancreatic juice and succus entericus, or secretion of the duodenum itself. Of these substances, by far the most important is the pancreatic juice with its tissue-digesting enzymes and its alleged specific toxicity incidental to auto-digestion or its own absorption into the blood stream. Another invariable feature of these fistulae is the loss of practically all nutriment taken into the stomach, with consequent rapid failure of nutrition and vital resistance. Efforts then should be directed toward neutralizing or removing the pancreatic juice and increasing the nutrition by rectal feeding, or even by jejunostomy. There is no agent which wholly stops the secretion of the pancreas. So far as is known, it is increased by the presence of food in the stomach, which inaugurates nervous impulses through the splanchnic nerves, causing a secretion rich in the pancreatic ferments, but poor in the alkaline elements. This action may be in part inhibited by atropin. In addition it is believed that the acid gastric juice acting on the duodenal mucous membrane forms a hormone (seeretin) which, having been absorbed by the blood, is carried to the pancreatic cells and there stimulates a secretion which is said to be rich in the alkalies and poor in ferments. Reasoning from these premises, it would seem proper to withhold all food from the stomach, or give only that which, like milk, does not excite gastric secretion, to give an alkali to further insure against gastric acidity, and to keep the patient under the influence of atropin. The chief dependence should undoubtedly be placed, however, on the dilution or mechanical removal of the secretion as fast as it appears, either by constant irrigation, as employed in the case reported today, or by some appropriate suction apparatus, as employed recently by Jones¹¹ and Williams,¹² or even, perhaps, by immersion of the patient in the constant bath. It may be noted in this connection

that the pancreatic juice, if removed soon after its entrance into the duodenum, is comparatively harmless since its most important ferment, trypsinogen, is relatively inert until activated by the succus entericus of the duodenum.

Before this audience, it is superfluous to insist on early operation, but it must be urged on those whose experience with abdominal traumas is only occasional. Hertle tells the story in his analysis of 109 cases of intestinal rupture: Of those operated on in the first 6 hours, 48% died; during the 7th to 12th hour inclusive, 54% died; during the 13th to 24th hour, 79% died; during the 24th to 48th hour, 93% died. Later than 48 hours, 80% died (in 16 cases the time of operation is not given). The abdomen should be opened on well-grounded suspicion,—when the diagnosis is sure the golden moment may have passed. The writer's experience has convinced him that in case of a pedestrian struck by an automobile, a concussion of the brain must be regarded as a fractured skull or brain laceration, and a contusion of the abdomen as a rupture of a viscus until proved otherwise, and that the reliable story of the passage of an automobile wheel over the abdomen justifies, or even demands, intervention.

IV.

CHOLELITHIASIS. AN ARGUMENT FOR EARLY OPERATION.*

BY JOSHUA C. HUBBARD, M.D., BOSTON.

AFTER the symposium on cholelithiasis at the meeting last year there is little to be said on the subject. There is, however, one point I wish to emphasize in this paper. The facts to prove it I shall not deduce from many statistics compiled from many sources, but from the records of one institution only, both autopsy and clinical. The general statement is this, that as soon as the diagnosis of gall-stones is made it is the duty of the doctor in charge, subject to possible complications, to advise operation. The

* Read before the Section of Surgery of The Massachusetts Medical Society, June 8, 1915.

profession and the public have been brought to the realization of the necessity, in certain diseases, of immediate or early surgical treatment. Appendicitis, for instance, is now recognized by the public as a disease for surgical treatment. In fact, I have sometimes found the physician recommending operation more strongly than the surgeon. In this list of diseases for early operation cholelithiasis has a place, I believe, and I think I can prove the truth of my statement, that with the establishment of a diagnosis of gall-stones, the treatment becomes surgical. There may not be, as in appendicitis, the necessity for immediate operation, but the necessity does exist for early surgical interference.

Before going on to the actual proof of my belief let us review for a moment the life history, as it were, of a gall-stone. We know that gall-stones are found in the great majority of cases in the gall-bladder itself rather than in the ducts. The one necessary factor (according to Osler) for the formation of gall-stones is a low grade inflammation of the biliary tract. This inflammation is started by microorganisms, usually typhoid or colon bacilli, which, reaching the liver through the circulation either portal or general or by the common duct from the duodenum, induce a low grade cholecystitis.

The second requisite for the formation of stones is an obstruction to the outflow of bile from the gall-bladder. This may be due to a general muscular inactivity or to some mechanical obstruction.

This inflammation and stagnation then bring about in the gall-bladder a desquamation of the lining epithelium, an albuminous exudation and an increased formation of mucus and cholesterolin, and a precipitation of the biliary salts, and thus the formation of a gall-stone.

A stone formed in this manner remains quiescent in the bladder until its presence causes secondary changes or so much irritation that it is expelled through the ducts with the resulting symptoms of colic.

My proof that cholelithiasis is a disease for operative treatment is established from two sources, clinical and autopsy. First, let us consider the clinical proof.

In a series of 220 cases operated upon at the City Hospital, 31 died. Why did these 31 die? Because they were more seriously diseased than those who recovered. This was shown by the greater frequency in them of chills, jaundice, enlarged liver, and a palpable mass in the region of the gall-bladder. The condition of the gall-bladder itself and the situation of the stones also showed greater severity of the progress. The bladder was inflamed, necrotic, perforated or contained pus in a large proportion, 8 out of 31, and stones in the ducts were found in half the cases, 16 in 31. The actual causes of death were sepsis, pulmonary complications, and a progressive general weakness. Why were these cases more severely diseased? Because the stones had been present so long in the gall-

bladder that they induced secondary changes in the bladder itself, infection, necrosis, perforation, or in the liver itself, or they had gradually been expelled from the bladder into the ducts. Could these stones have been removed from these patients before the secondary changes had induced a more serious condition, the operations would have been less severe. Removal of a stone from the common duct subjects the patient to a more severe operation than removal of stones from the gall-bladder. Could, therefore, these patients have been operated upon early, some, at least, would not have died, for the mortality of cholecystectomy or cholecystostomy is between 3 and 4%.

From a clinical point of view, therefore, operation as soon as possible after the establishment of a diagnosis offers the best prognosis.

The advantage of early operation is shown even more clearly by an examination of autopsy records. All autopsy records at the City Hospital were examined, to determine the cause of death where a gall-stone was found post mortem. Cases from the surgical wards in this list were few, for the stones had been removed ante mortem by operation. Cases dying in the other divisions of the hospital, therefore, make up the greater number of the cases. There were 108 autopsies where a gall-stone was found. In 76 cases the stones were found in the gall-bladder only. Of these 76, nine died as a result of the presence of the stones, the causes of death being hepatitis, cancer of the gall-bladder, pancreatitis and abscess of the liver.

Among the 108, 32 had stones which had passed from the gall-bladder into the ducts. In 14 of these death was due to the gall-stones, the causes of death being abscess of the liver, peritonitis, and cholecystitis. In other words, gall-stones in the gall-bladder killed in 11%, while stones in the ducts killed in 43%. What could be a greater argument than this for operating early, while the stones are in the gall-bladder? The relative mortality that this series of cases of gall-stones shows to exist between those operated upon early and those treated surgically, late or only after complications have arisen, is convincing evidence for prompt surgical interference as soon as the diagnosis has been established.

I collected these figures with an unbiased mind and not to prove any preëxisting idea of my own. They showed so clearly the advantage of early operation that I have ventured to bring them before you. It seems to me now that it is our duty to educate the public to accept operation as readily in cholelithiasis as in acute appendicitis.

These clinical and autopsy records, if they show anything at all, show that the prognosis in cases of gall-stones is dependent on the length of time the stones have been present. In a given individual the earlier they are removed the better the prognosis.

V.

A BRIEF CONSIDERATION OF ACUTE PANCREATITIS
WITH CASE REPORTS.*

BY CHARLES E. DURANT, M.D., HAVERHILL, MASS.

I SHALL make an effort in this paper briefly to review the subject of acute pancreatitis; in addition, I shall present abstracts of five cases, which I have personally observed, and in four of which I have operated.

It is well understood by those who have had personal experience, and by those who have made a careful study of the literature, that the condition in question is one of the greatest importance, because: (1) it is relatively infrequent; (2) it is not always easy of recognition, and therefore, perhaps often overlooked in the beginning; (3) in some instances, it is tremendously rapid in its course and fatal in its termination, and (4) in all cases, early diagnosis and prompt operation are essential to success. Granting the truth of these propositions, there should be some advantage in restating the problem, with the idea at least of renewing old impressions grown dim, it may be, through the inexperience of scant opportunity.

As regards the cause of pancreatitis, one is surer of the fact of infection than he is of its *modus operandi* in many cases; the colon bacillus is, as one would expect, the organism most commonly present. One of the most significant clinical facts concerning pancreatitis is the frequency with which it is associated with gallstone disease. In passing, the citation of a few statistical groups may be made, to indicate how often the two conditions are found together. Thus, Egdahl in 105 cases found 42% complicated with gallstones; Körte, 47% in 44 cases; Dietrich, 50% in 16 cases; in the London Hospital, 11 autopsies in cases of acute pancreatitis, showed gallstones present in 7, or 63.6%. It is unnecessary and superfluous to multiply statistics, for the proportion is practically the same in the reports of other observers. Such figures are significant, inasmuch as they establish definitely a relationship which cannot be disputed.

Opie demonstrated years ago that a calculus impacted in the ampulla of Vater caused regurgitation of bile through the duct of Wirsung, and that bile injected into the pancreatic ducts, produced pancreatitis of typical pathology. These observations are fundamental and serve to explain in a definite way the development of certain cases of pancreatitis associated with cholelithiasis.

The problem would indeed be simple, if calculous impaction of the ampulla of Vater were always found, for the rationale of the process would be at once apparent. But it is important to note that when gallstones are present, only 20% are found in this location. Moreover, it has been shown that a calculous impaction of the

common duct in the ampulla will be followed by direct regurgitation of bile into the duct of Wirsung in only 30% of the cases. This is to be accounted for by anatomical variations. It is obvious, therefore, that infection of the pancreas in gallstone cases, involves other factors than simple regurgitation of bile through mechanical influences. Efforts to explain the mechanism of infection in cholelithiasis without impaction in the ampulla have been made by Deaver, who claims direct and definite communication between the lymphatics of the gall-bladder and the pancreas, but recent experiments indicate that invasion by this route cannot be proved and is, moreover, improbable.

In addition to the work of Opie, many other laboratory experiments have been made by injecting solutions of various chemicals, extracts of intestinal juices, diluted bacterial cultures, etc., into the pancreatic ducts and into the pancreas itself. The story of these experiments is long and technical; the results are neither uniform nor definite, and their recital would be unprofitable in a clinical survey. The conclusions of Polya, quoted by Sir Frederick Eve, may be accepted as a brief and fairly complete resumé of our present knowledge. "Typical pancreatic necrosis, with hemorrhages, fat necrosis, and a rapidly fatal course, may be originated most certainly, with strongly active trypsin solution, less constantly, by duodenal contents, and by bile mixed with bacteria, rarely by the contents of intestinal fistulae, and extract of intestinal mucous membrane, and only exceptionally by bacteria alone." Can it be denied that the problem is complex and needs further elucidation?

Cases of pancreatitis have been reported in association with non-calculous inflammation of the gall-bladder and bile passages, which presumably bear the same relation to the biliary infection as has been referred to in gallstone cases with impaction in the choledochus—at present unexplained.

In cases arising in the course of such diseases as typhoid and gastric ulcer—a not inconsiderable number—direct invasion of the duct of Wirsung or the duct of Santorini may be assumed. On the other hand, when pancreatitis occurs as a complication of mumps, and quite a number of cases have been reported, we may reasonably conclude that infection takes place through the blood stream. Clinical observations seem to indicate that males are more often affected than females, that the subjects of pancreatitis are likely to be obese, and that alcohol has some apparent predisposing influence. Moynihan states that a very considerable number of cases occur in pregnant women at about the third month of pregnancy.

I need dwell but a moment on the pathology of pancreatitis. The gland is swollen and soft; mottling due to hemorrhage is seen; also fat necrosis, both within the gland and on the omentum and mesentery. In certain cases, extensive fat necrosis even to complete sphacelation of the

* Read before the Section of Surgery of The Massachusetts Medical Society, June 8, 1915.

entire gland may occur with great rapidity. In the less severe forms of infection, the necrotic process is more limited and a localized abscess results, often invading the peripancreatic fat, and sometimes occupying a considerable space in the lesser omental bursa. Serous or bloody effusion is usually present in both greater and lesser sacs. General septic peritonitis is frequently the terminal event, either by direct extension of the process itself, or as the result of the rupture of an abscess.

Mikulicz suggests the pathological analogy between acute pancreatitis and phlegmon, in which the process shows different degrees of intensity, varying from the mildness of simple furuncle to a more or less extensive destruction of the organ, with involvement of the retro-peritoneal tissues and the sub-phrenic space. Körte goes so far as to say that "Only a small number of cases of pancreatitis reach the stage of necrosis, the majority dying from acute inflammation"—and of course, toxemia—"before that stage is reached."

The clinical picture of this condition is strikingly illustrated by Fitz in his classic monograph of 1899.

"Acute pancreatitis," he says, "is to be suspected when a previously healthy person, or sufferer from occasional attacks of indigestion, is suddenly seized with violent pain in the epigastrium, followed by vomiting and collapse, and in the course of 24 hours, by a circumscribed epigastric swelling, tympanitic or resistant, with a slight rise of temperature."

This description is concise, exact and complete—nothing of importance has been added to it, and all subsequent observations have confirmed its value. The clinician will do well to remember these words of Fitz, for they will help him easily to visualize and more readily to recognize "one of the most serious diseases which he is ever called upon to treat."

Notwithstanding this clear cut definition, acute pancreatitis is by no means always easy of recognition. After many years of extensive experience in abdominal surgery, the late Dr. Maurice H. Richardson remarked as follows: "I have never seen enough of this disease to feel confident of my diagnosis when I have made it. From the nature of things, no man is likely to recognize with confidence the disease—from its infrequency, if for no other reason. Were these acute infections of the pancreas—or for that matter of the upper abdomen from whatever cause—as common as infections of the appendix, the surgeon would soon be able to recognize the clinical picture. As it is, he sees so infrequently that picture, that a study of it reminds him of the truth, but does not recall it vividly and beyond mistake."

A history of previous attacks of epigastric pain or distress is often present, as Fitz remarks, in cases in which pancreatitis should be suspected; these attacks may be due to ulcer, gall-stone colic, or to slight pancreatic hemorrhages,

which are said often to precede a definite attack of acute pancreatitis. Cyanosis of the face or abdomen has been referred to by Halsted and others as of special significance; it is present in some cases, but certainly not in all. One recent writer lays considerable stress upon a "splitting backache," particularly marked in the left lumbar region. This he regards as of almost pathognomonic value.

In differentiation, one must first give careful attention to the possibility of perforative lesions of the gall-bladder, duodenum and stomach. Perforation of the gall-bladder, while by no means rare, is not common, and is most likely to be preceded by definite historical evidences of cholelithiasis, or general and localized manifestations of acute inflammation. The pain of perforation of the stomach and duodenum is, often enough, overwhelmingly prostrating at its onset, perhaps even more so than in pancreatitis, and as a rule, less easily relieved by morphine. One observes, furthermore, in this condition, the development of generalized, board-like rigidity of a very distinctive type. In pancreatitis, on the contrary, the rigidity is less marked, and is limited to the epigastrium, where one finds in addition tympanic distention, with perhaps, a sense of deep resistance. Moreover, evidences of shock and collapse, in association with perforation, are of relatively short duration, and patients seen within a few hours after the initial pain, are not usually found in shock. This free interval, so to speak, persists until the appearance of peritonitis, which changes the picture for the worse. In pancreatitis of the fulminating type, evidences of shock and great depression continue from the beginning.

It is my belief that acute pancreatitis is more often mistaken for acute intestinal obstruction than any other condition. The initial vomiting, and rapidly developing distention of the upper abdomen, are certainly suggestive. In pancreatitis, there is, furthermore, marked inhibition of peristalsis from shock and toxemia, so that the passage of flatus is limited and difficult, and enemata in this condition are by no means followed by satisfactory evacuations either of gas or fecal matter. If one carefully analyses the symptoms, however, he will find that the pain of pancreatitis is more persistent, not intermittent or colicky in character, that the degree of early shock produced is much greater than in ileus, and that flatus can be, and usually is, passed in small quantities, voluntarily or after the use of enemata. Another point of importance in favor of the presence of the pancreatic lesion, is the localized tenderness in the epigastrium, which is marked and persistent, as has already been pointed out, and which one fails to find in early high obstruction in the intervals between the periods of intestinal spasm.

In spite of the difficulties which all admit, it seems to me that a careful, even though rapid analytical consideration of evidence along these lines, will enable the observer to arrive at a

reasonably probable diagnosis of pancreatitis in most cases, if he holds it in his mind as a possibility when dealing with the acute emergencies of the upper abdomen.

The prognosis in pancreatitis depends upon the intensity of the inflammatory process. In the hyperacute variety, it is obviously exceedingly grave; it could not be otherwise when we consider how rapidly wide-spread necrosis occurs, accompanied as it often is, by a prostrating and deadly toxemia. In the milder grades of inflammation, showing less tendency to rapid necrosis, the outlook is more favorable. If suppuration occurs, and the condition is recognized before the development of peritonitis or other complications, there is a fair chance. Without attempting to particularize by the citation of statistical data, which even now are somewhat limited, it may be confidently asserted that early diagnosis and prompt operation have materially improved the prognosis, and further improvement can be looked for only along these lines. Admitting the truth of these generalizations, it is clear that an early diagnosis is imperative, and that even a reasonably probable diagnosis constitutes an absolute indication for operation.

The operative procedure may be described as follows: A median epigastric incision is made; if pancreatitis is present, a quantity of dirty, brownish fluid will usually escape. This is suggestive, but not distinctive. It may be said in passing, that in the early cases where surgical interference was practised, drainage of this fluid without direct attack upon the pancreas itself was considered sufficient; such simple measures were proposed by Hahn and followed by him. Pels-Leusden, Wolsey and others, all of whom have reported successful cases. An examination of the omentum will reveal the presence of the small, yellowish-white spots of fat necrosis in scattered areas. This sign is always definite, and positive evidence of a lesion of the pancreas, and further procedure should be directed towards that viscus. To reach it, three routes have been employed: first, above the stomach through the gastrohepatic omentum; second, below the stomach through the gastrocolic omentum, and third, through the transverse mesocolon. The objection to the route above the stomach lies in the fact that when the stomach is in a high position, it does not give easy access to the pancreas, and for this reason it is not desirable. The route through the transverse mesocolon, while giving easy access to the more central portions of the gland, does not allow one readily to reach its lateral extensions, unless a large rent is made in the mesocolon, which is to be avoided. Furthermore, this approach affords no opportunity to protect the lower abdomen from dangerous extravasation. The best route of all, it seems to me, lies through the relatively thin and less highly vascular gastrocolic omentum. A longitudinal tear of moderate length brings one at once to the pancreas. As much of the continuity of the pancreas as can be reached, should be ex-

amined for softened areas, and wherever found they are readily and safely opened by blunt puncture with the urethral sound or some similar instrument. This method suggested by Körte is, in my opinion, of the greatest value. The instrument may be pushed into the gland in various directions, chiefly, of course, laterally, for a considerable distance, sufficient indeed to allow the introduction of a drainage tube directly into its substance. It is not possible, in my experience, to hold the tube in position by the use of sutures, but it may be retained with sufficient security by packing about it a good-sized gauze tampon surrounded by rubber dam. It is my impression if the patient does well, one should be in no hurry to remove either the tube or the tampon; I should think it had better be allowed to remain for a period of from five to seven days. I have not referred to the question of a counter incision in the loin, for the reason that such a procedure would be more applicable in subacute cases with abscess formation in the lesser sac. In cases where the trouble is limited to the head of the pancreas, Körte has suggested and practised mobilization of the duodenum to the left, following the Kocher procedure for impaction of stone in the ampulla of Vater. It is clearly the duty of the surgeon to examine the gall-bladder and bile ducts, to determine the presence or absence of cholelithiasis, but I cannot be persuaded that any operative interference should be attempted looking towards the removal of gallstones or drainage of the bile tract under circumstances so critical. If gallstones are found to be present, I believe their removal can be more safely accomplished at a later time, if the patient recovers. I apprehend that in most of these cases, vigorous measures will have to be employed to combat shock, which is usually present in considerable degree when the operation begins.

The following list of cases, briefly abstracted with some comments, is appended:

CASE 1. Male, 52, of alcoholic habits, and a previous history of repeated attacks of what was supposed to be gallstone colic. He was taken sick 48 hours before operation with a sudden, severe, epigastric pain, vomiting and constipation. The severity and urgency of his condition became increasingly apparent, and he was sent to the hospital. Examination showed an obese man, having a small, rapid pulse of poor quality, temperature 101.2°, face anxious, and quite cyanotic. A marked degree of shock was evidently present. Vomiting still persisted and the bowels did not readily respond to enemata, although some gas was expelled and a small quantity of fecal matter. There was marked distention of the upper abdomen, with tenderness on pressure over this area, and some degree of muscular spasm. The urine was free from sugar. On the question of diagnosis, perforation of the gall-bladder was thought of and could not be positively excluded; on the whole, however, the condition seemed to be too severe and to have developed too rapidly to warrant this conclusion. In perforation of the stomach or duodenum, one would have expected more generalized rigidity and less shock. Intestinal obstruction was

excluded by the escape of small amounts of gas and feces. A diagnosis of acute pancreatitis seemed probable. The abdomen was opened immediately; the peritoneal cavity contained a quantity of dirty, brownish fluid; spots of fat necrosis were found scattered widely over the omentum. The patient suddenly collapsed and died on the table. I made an incision through the transverse mesocolon exposing the pancreas. It was swollen throughout, softened, and, on section, showed the characteristic mottling of the acute hemorrhagic form of infection. The gall-bladder contained many calculi.

This case was typical clinically in all respects, and the result was what might have been expected. The presence of gallstones made it practically certain that biliary infection was also present—an additional feature of one of the classical types of pancreatitis.

At that time I should not have attacked the pancreas directly, but intended to drain the abdomen after evacuating the septic fluid. This view was based on a knowledge of the work of Hahn, Pels-Leusden, Wolsey, Halsted and others who had reported successful cases treated by this method.

The importance and value of early direct attack upon the pancreas for purposes of drainage and to prevent necrosis is now generally recognized. Necrosis often rapidly supervenes as has already been pointed out. In Körte's list of 38 operations, there were 34 in which this procedure was carried out; of these 18 recovered and 16 died. In four cases no effort was made to drain the pancreas—death resulted in each instance. No operation should be considered complete unless this is done.

CASE 2. Obese female, 53, single, admitted to the hospital Oct. 23, 1909, with a diagnosis of "gallstones." She complained of epigastric pain, moderately severe in type, vomited bile persistently, and belched great quantities of gas. The bowels could not be moved satisfactorily by repeated doses of cathartics and enemata. The upper abdomen was distended and there was marked tenderness, especially under the right costal border. The urine showed 1-2 per cent. of sugar on several examinations. The temperature had averaged about 101°, and the pulse, about 120 from the beginning of the attack. No jaundice. It was thought by the attendant that the patient was suffering from partial obstruction, or possibly gall-bladder inflammation. A conservative point of view was held as long as she did not grow rapidly worse. I saw her on Nov. 14, about three weeks after entrance, and the question of the presence of pancreatic disease was raised. It was, we thought, sufficiently strongly suggested to warrant an exploration, and on the following day this was done. Cloudy fluid was present and extensively distributed fat necrosis. The pancreas was investigated through the transverse mesocolon; it was generally swollen, and in one place, just to the right of the median line, very much softened. On making an incision at this point, there was a gush of pus. At no other point could definite fluctuation be detected. The opening was enlarged sufficiently to allow the introduction of a good-sized rubber tube. Gauze was packed around the tube, and the abdo-

men partly closed. Gallstones were present in the gall-bladder. The patient died on the second day from shock and exhaustion.

This case, presumably primarily of biliary origin, represented, in my opinion, an old infection of the pancreas, with involvement of the islands of Langerhans, as indicated by the presence of sugar in the urine. Incidentally, it may be stated that the presence of sugar in the urine, in the acute cases, is considered of no particular diagnostic value. The final outbreak of subacute inflammation and abscess was probably the result of a fresh infection. It seems reasonable to suppose that an earlier operation would have saved this patient. My procedure, in this case, was more radical than in the first case, in that I made a direct attack upon the pancreas, but I believe it would have been better to approach through the gastrocolic omentum.

CASE 3. Male, 36, mildly alcoholic, had grown rapidly obese in the last two or three years. History of stomach trouble for some time, and one or two attacks of "acute indigestion." The onset and rapid development in this case were absolutely typical. After a few hours' observation there remained no doubt in the minds of the patient's two medical attendants and myself as to the diagnosis. Extreme and agonizing pain, great shock, and persistent vomiting with upper abdominal distention and tenderness, characterized the picture. Considerable doses of morphine were required to relieve the intense suffering. Operation was considered, but the pulse was too rapid and of such poor quality that at no time did it seem in the least degree possible for the patient to withstand anesthesia. He died on the third day.

The autopsy showed that the peritoneal cavity contained a rather small quantity of cloudy fluid. The intestines were everywhere distended and congested although but little exudate was present. The pancreas throughout its entire extent was transformed into a soft, boggy, semi-liquid, greyish-green slough. The gall-bladder was normal, and contained no stones. No other pathological conditions were found. Apropos to the condition of the pancreas found in this case, Turnbull, quoted by Eve, commenting upon reported cases of complete sequestration, is inclined to doubt the possibility of its occurrence, and explains the finding as being due to necrotic peripancreatic fat. He cites two cases where "the house surgeon assured him that the whole pancreas had sloughed through a laparotomy wound, but in both instances, the pancreas was found in its normal position at the autopsy." In spite of the view of Turnbull, I am absolutely sure that the whole pancreas sloughed in this case.

One can scarcely imagine a case more typical of the fulminating variety than this, both clinically and pathologically. Perhaps operation would not have saved the patient; it certainly should have been done.

CASE 4. Female, 37, married, four children. History of irregularly recurring epigastric pains for five years, attacks always came on just after meals, never at night and were usually relieved by vomiting. Morphine had to be given several times. She

was told on different occasions that she was jaundiced and gallstone trouble was the cause assigned.

Twenty-four hours before operation she was seized with extremely violent epigastric pain; there was no vomiting. Morphine was given, but she grew rapidly worse, and was sent to the hospital with the diagnosis of probable acute pancreatitis. At entrance, her temperature was 100.5°, pulse, 120, of poor quality; patient looked very sick; epigastrium was distended and tender. Immediate operation—epigastric incision, brownish fluid in peritoneal cavity; fat necrosis on the omentum and mesentery; pancreas exposed through transverse mesocolon; found to be generally swollen and quite soft. It was punctured in two places near the middle with a steel sound, which was pushed into its substance readily in both directions. Rubber tubes were inserted into each puncture, and two cigarette drains were carried down to the pancreas. No gallstones were present. Following the operation, the patient did well; pulse steadily declined and registered 70 on the fourth day; temperature was normal on the ninth day. There was a profuse discharge of foul-smelling pus throughout the patient's stay in the hospital, a period of 50 days. She was discharged in excellent condition, with a sinus still persisting. This fistula did not heal, and a little more than a month later, she was readmitted. After being in the hospital about a week, a calculus the size of a small pea came away; from that time on, the discharge grew progressively less and about six weeks later the wound was soundly healed. The patient suffered from occasional mild attacks of epigastric pain for six months following the closure of the wound; ten months later, she gave birth to a child. She now states that she has been in absolutely perfect health for a year.

Körte remarks that "The time of healing in all those cases in which there was a discharge of necrotic pieces of the gland or fistula formation was very long—from two to seven and a half months. In only a few of them in which there was such discharge was the healing completed before one and one-half months."

CASE 5. Male, 67, previous history of indefinite stomach trouble, and at least one attack of pain in the upper abdomen requiring morphine for its relief. Aside from this and the general "slow down" of advancing years, his health had usually been very good. Seventy-two hours before I saw the patient, he was taken with sudden, severe epigastric pain and vomiting. Morphine in considerable doses was given. It was thought that he had intestinal obstruction and immediate operation was advised. He declined to follow this advice because of Christian Science leanings and rather compelling Christian Science influences, so it is said. When I saw him, he was suffering greatly from pain in the upper abdomen, tossing about the bed, and often getting up and walking around the room. The abdomen was generally distended, but especially so in the epigastrium, where there was very marked diffuse tenderness, an indefinite sense of deep resistance and muscular spasm. His pulse was 100, of poor quality; temperature slightly subnormal. I was told that his bowels had moved but slightly since the beginning of the attack and that he had vomited frequently. He was taken to the hospital and operated upon at once. When the abdomen was opened, spots of fat necrosis

were quickly evident; there was considerable fluid in the peritoneal cavity; the intestines were greatly distended. The gastrocolic omentum was torn through and the pancreas exposed. It was swollen and soft. I made several punctures with a steel urethral sound, but nothing escaped from the punctures except bloody fluid. Two good-sized rubber tubes and two cigarette drains were placed in contact with the pancreas. No gallstones were present. The abdomen was partly closed.

Following the operation, the distention increased steadily, became most distressing, and could not be relieved by enemata. The patient vomited persistently after the first two days in spite of lavage; on the third day, he became irrational and died deeply stuporous on the seventh day of general peritonitis.

The gravity of this case was recognized in the beginning when the patient had his best chance. If he had seen fit to accept the suggestion of his medical attendants, even though they thought he had ileus, his life might have been saved, especially as the process of disintegration in the pancreas was not found far advanced at operation. Toxemia seemed to be out of all proportion to the local destruction of tissue. The diagnosis did not seem difficult.

There are no new conclusions to formulate as a result of this brief clinical survey. The urgency of the condition has been pointed out in speaking of the pathology, particularly in relation to the rapidity with which necrosis occurs in some cases; the overwhelming toxemia has also been referred to, as a factor of great importance in the same connection; this feature was well exemplified in case three. Even in instances where the onset is less severe and where more or less localized suppuration follows, such serious and probably fatal complications as subphrenic abscess, extensive suppuration in the peripancreatic fat, or general peritonitis may be looked for. The danger of hemorrhage in cases of persistent sinus was not mentioned in the body of the paper, but it is not to be forgotten. In view of all this, it seems unnecessary further to press the point except in closing formally to urge upon the practitioner the great importance of early diagnosis and prompt operation in acute pancreatitis.

I desire to acknowledge my indebtedness to Drs. Croston, Clarke, Donahue and Sullivan of Haverhill, through whose courtesy I was given the opportunity of seeing four of the cases here-in reported.

DISCUSSION OF THE PAPERS OF DRs. WALKER, CHEEVER, HUBBARD AND DURANT.

Dr. P. E. TRUESDALE, Fall River: In regard to perforating gastric and duodenal ulcers, my observations are limited to the experience of ten operative cases with two deaths. It seems to me that what happens to these patients in the first twelve hours is of considerable importance, and vitally affects the outcome. As a rule the patient demands relief, is given a hypodermic of morphia, and is put to bed. There he is quiet. The perforation remains open and fluid continues to escape. On the other hand, if he is left to his own devices, what happens? He does not go to bed. The last case I had gave this history: The patient was in bed and was taken with the pain at three o'clock in the morning, got up and sat in a chair. This gave him a spontaneous closure, stopping, in a measure at least, the escape of the contents of the stomach.

In applying a surgical procedure for this lesion, it seems to me that one should be guided almost entirely by the picture which is presented at the time of operation. Each surgeon must determine for himself what he can do most swiftly and effectively to close the opening and institute adequate drainage. The size of the perforation and the amount of induration surrounding it, makes closure easy or difficult. If the opening is small, the induration not marked, and the bowel lumen ample, a rapid and efficient closure can be made. Gastroenterostomy in the presence of such a picture is uncalculated for, and when done carries with it an added risk, increased by the presence of an acute lesion. However, if one should find the perforation to be $\frac{1}{2}$ to 1 c.m. in diameter, and the center of an indurated mass which has already encroached considerably upon the bowel lumen, the problem confronted is more difficult. Sutures are difficult to apply; they are often left under considerable tension, and when they cut out the opening may thus be made larger than it was originally. Final suture then should not be under tension. When the infolded mass is bulky and greatly encroaches upon the bowel lumen, gastroenterostomy should be done, even at the expense of an extra half hour. The wisdom of doing gastroenterostomy in every case is doubtful.

It is a notable fact, however, that occasionally the utterances of a master surgeon have led an average surgeon into deep water. For example, Dr. Deaver advocates gastroenterostomy in addition to closing the perforation. He has reported a series of thirty-two cases with one death, and he almost invariably does gastroenterostomy. He says that ten or twelve minutes more are utilized in doing gastroenterostomy. All this must be taken into account when considering the chances of recovery for the patient. Therefore, it seems to me that when you are in doubt about doing gastroenterostomy, don't do the gastroenterostomy.

Dr. D. F. JONES, Boston: I will add just one word in regard to Dr. Cheever's paper concerning perforating ulcer. Dr. Cheever gave the impression that the reason he cured his 32 cases was because he had done a gastroenterostomy. He neglected to say that all of the cases which recovered had been operated on in twelve or fourteen hours after they were diagnosed. This is the whole point of the paper, and not his gastroenterostomy.

I wish to mention a case in my experience where there was a duodenal fistula, probably due to necrotic abscess, with sloughing of the duodenal wall, and a discharge of all the stomach contents through the duodenal fistula. The man went down to the lowest possible point, and when he was about to die we decided to do a jejunostomy. That was done and the man was fed by a tube through the jejunum. This kept the wound dry, and gave the wound a chance to heal. We were able to feed him by the jejunostomy for some three weeks. At the end of that time the fistula got along perfectly well.

In a number of reported cases of injury to the jejunum or duodenum, gastroenterostomy was done. It seems to me that a jejunostomy is the more satisfactory operation, in that the stomach contents do not have to be pushed through the injured intestine at all, but you can feed your patient by jejunostomy.

In regard to Dr. Durant's paper, I was sure that he meant to cover the whole field, and I therefore looked up the cases of pancreatitis at the Massachusetts General Hospital to see how frequently they occur. I found that in ten years at the Massachusetts General Hospital, that is, from 1904 to 1915, there were but 28 cases operated on surgically. Those cases were divided as follows:—acute, 10 with six deaths, or 60%; acute hemorrhagic pancreatitis, five cases, five deaths; chronic, 12 cases with three deaths, 25%. There was one case of gangrenous pancreatitis and one case of abscess of the pancreas, both of which recovered.

In regard to gall-stones in connection with pancreatitis, I think they are almost always present, although in the cases at the hospital there were but six cases of gall-stones, at least where they were noted at the time of operation. There was one case of ulcer of the stomach in connection with the pancreatitis.

Another interesting fact is that in the 28 cases, seven of them gave a history of previous attacks of pain, and in six of the seven cases there were no gall-stones present to give the symptoms. You will find, I think, in a very large percentage of cases of pancreatitis, attacks of pain which cannot possibly, I believe, be distinguished from gall-stones. The diagnosis, as Dr. Durant says, is very difficult. If one could see them more frequently one could undoubtedly make a diagnosis much more often.

While it may be of some importance to operate on these cases early, it is a fact that it depends greatly upon the conditions found at the

operation,—that is, the severity of the onset, as to whether the patient gets well or not. It also depends on the amount of blood or fluid in the abdominal cavity. As you know, there is the apoplexy of the pancreas in which patients die immediately, are found dead on the street. Those cases we do not see surgically because they do not get to the hospital alive. Then we have acute pancreatitis, in which there is no blood or bloody fluid, but in which there is straw-colored fluid. Of those cases, 40% recovered. In chronic pancreatitis cases there is no fluid whatever, simply a thickening of the pancreas. Practically all of these cases got well. Those cases are usually found in the course of other operations, usually operations for gall-stones. In the course of the gall-stone operation, the surgeon puts his hand down and examines the pancreas. It is found hardened and thickened. That is called chronic pancreatitis. Dr. J. H. Wright says that there is no condition like this found when patients come to autopsy. I do not know what becomes of the thickening; it is certainly there at the time of operation, but Dr. Wright says it is never there at autopsy.

In regard to Dr. Hubbard's paper, I feel that there can be no question that he is right in saying that whenever a diagnosis of gall-stones is made, the patient should be operated on. I think we are all coming to see that more and more.

Dr. F. B. LUND, Boston: I have very little to add, but I want to say one or two things. Dr. Walker's paper shows that there has been of recent years a great improvement in the matter of early diagnosis, and in consequence, a great improvement in mortality. It is very encouraging. The first successful operation for perforation of the stomach on this continent was performed by Dr. Atherton of Fredericton, New Brunswick, who was one of the earliest house officers at the Boston City Hospital. Perforations of the gall-bladder have been about as severe and more fatal in my experience than perforations of the stomach.

Dr. Hubbard's paper brings out the importance of early operation in gall-stones. We used to wait for an interval in appendicitis, but we do not do that any more. We also used to wait for an interval in gall-stones, but I have found that operations on acute gall-bladders, even gangrenous ones, often give as good result as waiting for an interval. While waiting, the trouble often gets worse, and I once saw pancreatitis result.

In regard to Dr. Durant's remarks, I have found jejunostomy very valuable in saving life through enabling a patient to be fed after operation for perforation. I had a patient recover who had a perforation operated twenty-four hours after it took place. The operation was followed by subphrenic abscess, and then by empyema, requiring operation, which weakened him so that I had to do a jejunostomy to feed him. After his strength had been restored by this, a gastroenterostomy was done, and he made

a perfect recovery. We must never forget the possibilities of jejunostomy in these cases. Dr. Durant's paper covered the ground very thoroughly. I think there is a good deal of truth in the German author's statement that he quoted, who stated that, while there is a good deal of sloughing, which is thought to be sloughing of the pancreas, it is really the peripancreatic fat and not the pancreas that is concerned. I read a paper on this subject a good many years ago (fifteen, I think), and in one of my cases which came to autopsy there was a good deal of sloughing through the wound, which we thought came from the pancreas. At death a normal pancreas was found, so it looked as if this tissue must be peripancreatic fat. I am sure that sometimes a portion of the pancreas sloughs, but I think a great deal thought to be pancreas is merely peripancreatic fat.

Dr. AGNES C. VIETOR, Boston: I would like to ask whether there are any statistics of the condition of the gall-bladder in acute pancreatitis, other than those relating to gall-stones.

Since, according to present evidence, it is the infection of the gall-bladder that is fundamental in the production of gall-stones, would it not be well for those of us who may meet cases of acute pancreatitis, to note not merely the presence or absence of gall-stones, but also the presence or absence of non-calculous cholecystitis?

Dr. I. J. WALKER, Boston: It is surprising to learn the number of these patients who have been treated for stomach trouble, indigestion and various things like that, and have, perhaps, been rather indifferently treated. It seems to me that the important part in the prevention of these cases of perforation is to treat conscientiously the chronic ulcer of the stomach, or duodenum.

And again, Dr. Truesdale spoke of these patients wanting relief. That is, of course, perfectly true. The most of them need morphia, but they should not be left to stay in the house, and let things happen there. They should be sent to the hospital at the start, while the chance of recovery from operation is good.

Dr. C. E. DURANT, Haverhill: Dr. Lund's statement in reference to the condition of the pancreas in his case fully confirms the view of Turnbull which I quoted. In my case, however—probably an exceptional one,—there was no question of practically complete sphacelation, for the pancreas was most carefully and thoroughly examined. The degree of destruction in so short a time was astonishing.

In reply to the question as to the frequency of non-calculous cholecystitis in association with pancreatitis, I am not able to make any statement based on statistical information. Furthermore, I am not aware of any reported cases where bacteriological investigations have been made looking towards the determination of this phase of the question. It is surprising that Dr. Jones, in the Massachusetts General Hospital cases, found fat necrosis reported in but 40%; I think this rather unusual, for Mikulicz, Körte,

and others report its presence with much greater frequency.

In operating in gall-stone cases, I have never been certain of my ability to make a diagnosis of chronic pancreatitis by palpation, and therefore, I was glad to hear Dr. Jones say that Dr. Wright feels that there is no such thing as chronic pancreatitis determinable by the operating surgeon.

Original Articles.

A PROPER CLASSIFICATION OF BORDERLINE MENTAL CASES AMONGST OFFENDERS.

BY V. V. ANDERSON, M.D., BOSTON.
Municipal Courts.

FOREWORD.

THE problems of our Courts, even more than those of the Psychiatrist, are *failures of mental adaptation*.

A great host of repeated offenders,—recidivists who seem to be able properly to adjust themselves to Society's customs and institutions,—have as a fundamental basis of their lack of adaptability a mentality that deviates from normal, and would seem, if looked at purely from the social point of view, to be all of them defectives. They have been so termed by many observers.

Certain recent, purporting to be scientific, studies indicate the proportion of mental defectives among court cases as 89%, a condition wholly out of keeping with the common sense experience of judges, probation officers and others who have been dealing with delinquents. If such a universal cause could be discovered, why then a solution of the crime problem would be simple indeed; but such reports are not taken seriously inasmuch as the methods used were open to such grave criticism as to render the findings, for practical purposes, useless. Suffice it that the most reliable work done indicates a lower percentage of mental defectives among offenders in general, ranging from ten to thirty per cent. But what of the remaining seventy to ninety per cent? It has been on this particular problem that most of our interest has been centered, and this paper, while principally in the interest of a proper classification of borderline cases, forms an introduction to a series of contributions which will be made, calling attention to two very important types that have been overlooked.

One of the most urgent problems in the proper development of medical expert work in our criminal courts, is a workable classification of those borderline mental cases which belong neither to the feeble-minded nor the insane, and are yet clearly abnormal in mentality.

This paper will discuss the plan we have adopted of classifying these border line mental types in the Municipal Criminal Court of Boston. No reference is made to the various psychoses, to those suffering from alcoholic deterioration, to the epilepsies, etc., for obvious reasons. Our discussion simply has to do with a borderline group of individuals found amongst delinquents in general, who apparently have been very difficult to classify and about whom a most confusing terminology exists. They have been a source of much trouble to social workers, to criminal courts, and to various institutions. They seem unable to profit properly by any sort of treatment, and are suspected by those intimately associated with them of being "crazy," "born criminals," and what not. A more scientific terminology popularly applied is "moral imbecile," "moral insanity," "emotional defective," "defective delinquent," etc.

The terms being apparently used interchangeably, one physician may classify an individual as a moral defective, while another will diagnose him as a defective delinquent, and still another may call him an emotional defective, and so on. All the while the examiner may have only a vague conception of what he really means by his terminology.

Now for practical use in the study and treatment of offenders a classification should be definite, workable and based on demonstrable facts, rather than loose generalizations. Nothing is gained by categorizing individuals unless our classification conveys such well defined knowledge of types as will serve a practical end.

The term "defective delinquent" is being used by different examiners to define markedly divergent types. To some it means delinquent individuals who as a result of mental examination are found to be defective in mentality. Then the logical classification, from a mental standpoint, would be mental defectives. But other examiners are apparently using the term "defective delinquent" to cover a class of individuals who as a result of careful mental examination give no evidence of mental defect; but their conduct is abnormal, they have certain character defects, and they are anti-social,—they, forsooth, must be defective anyway, so why not call them defective delinquents? It is an easy way out of the difficulty.

Then there is a tendency to use the term to fit otherwise normal individuals who have criminal tendencies, presupposing that repeated criminality is proof of a defective mentality; a correlation wholly unjustified, unless we use the term defective as a social classification, and not as a mental in other words, unless we are going to make "defective" refer simply to conduct that is abnormal and not in keeping with social standards, rather than back to its definite cause in a particular type of mentality.

Altogether we have presented to us a rather loose and confusing symptomatology connected with the term "defective delinquent," and when

the state is prepared to have these individuals committed to separate institutions, the difficulties of definition one fears will be insurmountable.

It would hardly seem necessary to discuss seriously such a classification as moral imbecile or moral insanity, did it not persistently crop up in the literature, and did not physicians now and then make use of such a diagnosis. To justify this classification one would have to presuppose the existence of a special moral faculty, an ethical department separate and distinct from the rest of the mental life; a presupposition wholly unjustified in the present light of scientific methods of studying the human mind.

In fact, we have come to realize that our moral judgments are inextricably mixed up with social judgments; that general intelligence, learning, experience, etc., are brought into play in the exercise of every moral judgment; that millions of brain processes are involved in every thought and act, and conduct is an expression of the whole machinery at work; that there is no ground for the presupposition of a separate sense that sits in judgment, approving or disapproving of our actions. In short, a mentality incapable of forming moral judgments is likewise incapable of forming normal judgments along other lines, and is (*ipso facto*) a defective mentality, and is demonstrable by a thorough examination of general intelligence, judgment, reasoning capacity, etc. These are *mental defectives*, and not moral imbeciles.

But the term is more frequently used to refer to a type of distinctly anti-social individuals who are not defective in mentality and are not lacking in capacity to form moral judgments, nor are they devoid of moral feelings, but are hampered with a constitutional instability of their nervous system which renders them very impulsive, vehement, inhibitionless and emotional; in other words, they are easily unbalanced, and thus especially liable to serious social difficulties in a complex environment. These are *psychopaths*, and not moral imbeciles.

A careful study of other supposed cases of moral imbecility brings to light victims of a vicious social environment, early immoral teachings and practices, individuals suffering from mental conflict, etc., etc. Healy has well said that the great probable sources of difference of opinions as to the existence of such a type is in the extensive theorizing and the lack of careful statement, either of definition, or of the results of survey of all investigable elements of mental life.

Certainly if in all cases of so-called "moral imbecility" the examiner would make a thorough study and record of the various mental abilities and disabilities of his patient, the self-contradictions so frequently found in the literature would hardly be possible. For our own part we find no need for the term as we have not yet run across a single case of moral imbecility or moral insanity.

But what serious objections are there to using the term "defective delinquent"? There are none, if by it we mean those delinquent individuals who are defectives. In other words, if we draw the line somewhere, restricting it to the mental defectives, making the term workable, and not allow it to cover several divergent types; else those of us who are having to do the practical work of classifying mental cases in courts and penal institutions will find the anomalous situation of a group of defective delinquents being composed of some offenders who are clearly *mental defectives*, some who are not defectives but are *psychopaths*, and others who are neither defective nor psychopathic in mentality, who are not pathological but psychological types,—the *mental delinquents*. Three distinct types, requiring entirely different treatment and offering a wholly different kind of prognosis from the standpoint of reformation. In other words, we will find that the term "defective delinquent" is a social classification and not a mental, and is being used to refer to acts, anti-social in character, which from the mental side have their basis in wholly different types of mentality.

As previously stated, there is no objection to calling those amongst our courts and penal cases, that are defective in mentality, "defective delinquents," nor is there any objection to calling those that are insane, "insane delinquents," and those that are epileptic, "epileptic delinquents," if we do not mean to imply that they belong to mental types different from the mental defectives, the insane and the epileptic. (But what is the use of it all? The very fact that one mental defective has been caught in his anti-social conduct, and another has escaped, is not sufficient grounds for a difference in mental classification of the two.)

If we do imply that the defective delinquent is a different type from the mental defective, then on what logical basis do we use the term as a mental classification,—for how can they be defectives and still not mental defectives? A contradiction. The term defective used with reference to the mind of an individual should carry with it a lack of normal mental development and should have a very definite meaning to us. This condition is demonstrable by exact methods of measurement. The term defective, used with reference to the social aspect of one's conduct, may as well be applied to those with a mentality that is disordered, as those with a mentality that is defective, and from such a point of view the majority of the fifty-odd thousand delinquents coming before our courts in one year could be classified as defective delinquents. The fact is that the term is being used constantly to refer to a group of individuals who, when their abilities and disabilities have been thoroughly and scientifically studied, give no evidence of mental defect, but are rated as adult in mental development. They are called defective delinquents, however, because they possess certain

personality maladjustments, certain character deviations, are distinguished by an anti-social line of conduct, are unreliable, changeable, impulsive, erratic, lacking in inhibitions, restless, at times showing great motor activity, becoming violent, and practically insane, under the influence of emotion, alcohol, drugs, etc. While under detention they clear up and give no evidence of psychoses or mental defect, only to have another outbreak when things go wrong in their environment. These are the *psychopaths*, as previously hinted at, and should not be confused with defectives. In institutions they give far more trouble than defectives, require a great deal more discipline, and seem little improved by any form of treatment. They are often absolutely unmanageable, and from the standpoint of our courts they require an entirely different disposition from the defectives, and must be clearly differentiated. One often finds enlarged thyroids; several cases seen by the writer had had both ovaries removed and had active changes in character dating from this incident, pointing, it seems, to the possibility of changes in certain internal secretions serving as a basis for this condition of nervous and mental instability. We must consider these individuals in the light of adjustment of their personality, rather than in terms of development of general intelligence, as we do the defectives; and realize that their anti-social conduct is due less to their stupidity, less to their lack of understanding of the demands of a normal social organization and inability to foresee the consequences of their acts, than it is to a disturbance in the coordination of the proper nervous mechanism; a poorly balanced mentality, rather than one that is defective. To call them "defective delinquents" confuses the issue, in that it emphasizes the social aspect, and is simply a social interpretation of their conduct; it does not point to the nervous and mental instability, rather than defect, that is the cause; furthermore, it allies them with the mental defectives, a type wholly different in mental makeup and treatment. The only logical classification that is free from confusion and serious criticism is the term "psychopath." This term fits so admirably the characteristics of this group, suggesting a relationship to the psychoneuroses and psychoses, rather than to feeble-mindedness, that we have used it as a definite classification of this type from the first.

It might be well to mention that among several hundred offenders examined we have found almost as many "psychopaths" as "mental defectives," suggesting that this condition may be of as serious importance as a basis of criminality as mental deficiency, and it may be that it explains the wide divergence in reports as to the percentage of defectives among criminals; some investigators claiming as high as 89%, others as low as 20%. The latter is possibly nearer the truth than the former, inasmuch as 89% undoubtedly represents the entire field of

this borderline group about which we are speaking, and thus includes not only the mental defectives but the psychopaths and mental delinquents as well.

Finally, after we have accounted for the mental defectives and the psychopaths among the recidivists, there still remains a very large group of repeated offenders who are not normal in mentality. Exact mental measurements fail to show any defect or sub-normality in mental development,—they are not defective. Carefully given psychiatric tests show no evidence of a psychosis: personality studies do not reveal any of the character makeup, temperamental peculiarities and disposition of the psychopath. They are not impulsive, poorly balanced and neurotic individuals; they are not lacking in inhibitions and liable to great emotional extremes, violent outbursts of temper, etc., as are the psychopaths, who are often quite conscientious and sincere and try repeatedly to do better, but fail because of their very marked nervous and mental instability. On the contrary, this particular type, the *mental delinquents*, have a fair amount of intelligence (depending upon the walks of life from which they come), a stable mentality, are cool and calculating, deliberate, planning out situations in advance, indolent and superficial, very selfish, egoistic, heartless, and even cruel at times. In them the self-preservative instincts are undisciplined and the nobler sentiments are lacking. They are strongly individualistic. In short, they possess a mentality that differs from the average or normal in that it is particularly non-social. It expresses itself as deviating purely along delinquent lines, and for this reason we have called them "mental delinquents," rather than defective delinquents, inasmuch as their mental condition is to be explained, as we shall show later, purely on psychological rather than pathological grounds; is acquired rather than innate. Their reformability is a well known fact, and thus their anti-social tendencies are not based on a lack of capacity for conduct in keeping with normal standards. These individuals have not had at the proper stage of their development those socializing influences which produce altruistic tendencies that discipline the instincts and emotions. The dominant note in their make-up is a non-moral and purely egoistic attitude, which tends to become more marked as character is formed around the unrestrained exercise of their primitive tendencies; tendencies which in themselves are normal, and present at certain stages of every individual's development, but which are checked when powerful inhibitions are laid down through fear of punishment, reward, expectation of social praise or blame, etc., which later on are to be reinforced through the growth of the higher and nobler sentiments that are of so much importance in the formation of character and the direction of conduct of individuals and societies.

We must remember in this connection that

character is not something born with an individual, but is built up on the native basis of disposition and temperament in the course of one's life and is the sum of acquired tendencies. There can be but little doubt that the sentiments constitute a large part of what is properly called character, and the organization of these we will remember, in the developing mind, is determined by the course of experience. Our judgments of value and of merit are rooted in our sentiments, and our moral principles have the same source, for they are formed by our judgments of moral value. Thus we can easily conceive how, if the raw material of virtue and vice are the same, and desires which in themselves abstracted from their relation to the higher self are neither moral nor immoral but simply non-moral, that the fundamental problem in a man's morality is his socialization by society. Now several things may take place to prevent this.

He may be so defective in mentality as to be unable to measure up to the standards and laws of a normal social organization, and thus constitutionally incapable of profiting properly by experience. In this case he is not a criminal but a "mental defective."

He may be so unstable and poorly balanced in mentality as to be continually liable to impulsive conduct, and thus incompletely socialized, as are the "psychopaths."

Or, as a result of acquired habits of thought and action, initiated during the formative periods of childhood and adolescence, he may have developed a character that is distorted and delinquent in its tendencies, and as a result he may be, for practical purposes, a "criminal" in his makeup. His environment may have focused upon him at some particularly weak moment a host of powerful influences, easily calculated to break down his weak inhibitions; especially is this true if the influences were exercised in the immediate service of desires springing directly from some one or other of the primary instinctive impulses. Now we have only to remember that habits are formed only in the service of instincts, and once initiated, how around them the entire character may be developed, for an acquired mode of activity becomes by repetition habitual, and the more frequently it is repeated the more powerful becomes the habit as a source of impulse, or motive power. In this way it is not difficult to understand how under particularly unfavorable circumstances the "mental delinquent," or, in popular speech, the "criminal type" develops.

I submit then that among our borderline mental cases we have three distinct types, recognizable as definite entities, the *mental defectives*, the *psychopaths* and the *mental delinquents*, each creating very definite social problems; each having a very definite constitutional makeup and requiring for proper treatment and solution an entirely different line of handling, as we

shall show in three papers that are to follow, entitled:—

- (1) "Mental Findings in a Group of Psychopaths."
- (2) "Mental Findings in a Group of Mental Delinquents."
- (3) "A Comparative Study of the Mental Defective, Psychopath and Mental Delinquent."

In these three contributions it is our desire to call especial attention to a series of thoroughgoing personality studies by which we were enabled to arrive at an explanation of the makeup of these distinct types.

These three definite groups constitute the very backbone of recidivism, and the institution of proper remedial measures, fitting the requirements of each particular group, would enable society to make immense strides in handling the crime problem.

THE RELATION BETWEEN THE GENETIC FACTORS AND THE AGE OF ONSET IN ONE HUNDRED AND FIFTY SEVEN CASES OF HEREDITARY EPILEPSY.*

BY D. A. THOM, M.D., PALMER, MASS.

FROM the records of the Monson State Hospital one hundred and fifty-seven (157) cases of epilepsy, each presenting in the family history one or more of the five mental defects into which I have arbitrarily divided heredity, viz., Epilepsy, Alcohol, Insanity, Feeble-mindedness, and Migraine, were studied in view of determining the relation between the hereditary factor in the forebears and the age of onset of the epilepsy in the offspring; but as the work progressed other problems were presented that could not pass unnoticed and they will be considered as they occur.

Of the total number of cases used for this study, eighty-two (82) were females and seventy-five (75) were males. One hundred and twenty-six cases had direct heredity (that derived from parents or grandparents), and thirty-one cases had collateral heredity (that shown in members of the family other than parents or grandparents). There were two hundred and ninety-three (293) heredity defects in the one hundred and fifty-seven cases, occasionally one member of the family having more than one defect, and in other instances two or more relatives being defective.

Table I. shows the distribution of the five genetic factors among the total of two hundred and ninety-three taints recorded.

* Read at the Triennial Meeting of the Harvard Medical Alumni Association at the Boston City Hospital on May 20, 1915.

TABLE I.—HEREDITY—ONE HUNDRED AND FIFTY-SEVEN CASES OF EPILEPSY.

	DIRECT (126).							COLLATERAL (31).											
	Mother.	Father	Mat. G. Mother.	Pat. G. Mother.	Mat. G. Father.	Pat. G. Father.	Total.	Sister.	Brother.	Pat. Uncle.	Mat. Uncle.	Pat. Aunt.	Mat. Aunt.	Cousin.	Uncle Unknown.	Aunt Unknown.	G. Father, Unknown.	G. Mother Unknown.	Totals.

Table II. is a record of the number of times that each defect was found alone, the different combinations that were formed by a grouping of two or more factors, and the number of cases in each group.

TABLE II.—SUMMARY.

	ONE DEFECT IN FAMILY HISTORY.	
	Cases.	Per Cent.
Epilepsy alone.....	44	28
Alcohol alone.....	23	14.6
Insanity alone.....	17	10.8
Migraine alone.....	9	5.7
Feeble-mindedness alone.....	3	2
	96	61.1

TWO DEFECTS IN FAMILY HISTORY.

Epilepsy plus alcohol.....	10	6.4
Epilepsy plus insanity.....	7	4.5
Epilepsy plus migraine.....	11	7.0
Epilepsy plus feeble-mindedness.....	2	1.3
Insanity plus alcohol.....	4	2.7
Insanity plus migraine.....	7	4.5
Insanity plus feeble-mindedness.....	0	
Feeble-mindedness plus migraine.....	2	1.3
Feeble-mindedness plus alcohol.....	1	.6
Alcohol plus migraine.....	3	1.9
	47	30.2

THREE DEFECTS IN FAMILY HISTORY.

Epilepsy plus alcohol plus insanity....	5	3.2
Epilepsy plus feeble-mindedness plus insanity	3	1.9
Epilepsy plus alcohol plus feeble-mindedness	1	.6
Epilepsy plus migraine plus alcohol....	1	.6
Epilepsy plus feeble-mindedness plus migraine	2	1.3

FOUR DEFECTS IN FAMILY HISTORY.

Epilepsy and alcohol and feeble-mindedness and migraine.....	2	1.3
	14	8.9

Ninety-six (61%) of the cases gave a family history of but one defect; forty-seven (30%) had two defects and the remaining fourteen cases (9%) had three and four defects.

Table III is but a further summary of Table II which brings out more clearly the total number of times that each one of the five genetic factors was met, either alone or in combination with one or more of the other factors, and also whether the heredity was direct or collateral.

TABLE III.—SUMMARY OF TABLE II.

	Alone.	Combined with Other Factors.	Total.	Direct Heredity.	Collateral.	Total.
Epilepsy	44	44	88 57%	49	39	88
Alcohol	23	36	59 38%	58	1	59
Insanity	17	26	43 27%	24	19	43
Feeble-mindedness	3	13	16 10%	13	3	16
Migraine	9	27	36 23%	34	2	36

It will now be seen that from the entire one hundred and fifty-seven cases epilepsy was met either alone or in combination eighty-eight times (or in 57% of the cases), alcohol fifty-nine times (38%), insanity forty-three times (27%), migraine thirty-seven times (24%), and feeble-mindedness sixteen times or 10% of the total number of cases. In 95% of the cases where alcohol, migraine or feeble-mindedness was the defective factor the heredity was direct, while only 56% of epilepsy and insanity came from the forebears.

Table IV represents the distribution of the hereditary factors in those ninety-six cases where there was but one defect. It goes further and shows the frequency with which each defect was met in the forebears and the total number of times in other relatives; also whether the heredity was direct or collateral. In seventy of the ninety-six cases, or 73%, the heredity was direct, in the remaining twenty-six cases collateral; in twenty-five of this latter group the mental defect was either epilepsy or alcohol.

TABLE IV.—NINETY-SIX CASES OF EPILEPSY SHOWING BUT ONE OF FIVE DEFECTS IN ANCESTRY.

	Mother.	Father.	Parents.	Mat. G. Mother.	Mat. G. Father.	Pat. G. Mother.	Pat. G. Father.	Total Cases Direct Hereditary.	Total Cases Collateral Hereditary.	Total Cases Direct Collateral.
Epilepsy	7	9	2	3	1	2	4	28	16	44
Alcohol	3	15	2	0	1	0	2	23	0	23
Insanity	3	3	1	0	1	0	0	8	9	17
Migraine	6	2	0	0	0	0	1	9	0	9
Feeble-mindedness	2	0	0	0	0	0	0	2	1	3

By referring again to Table II it will be noted that there were forty-seven cases showing two mental defects in the family history and that they were divided into nine distinct groupings. Epilepsy was combined with each of the other four factors in a total of thirty cases (64% of the group). Epilepsy plus alcohol, and epilepsy plus migraine were the two most common combinations; into these two groups fell twenty-one of the thirty cases. Mother epileptic and father alcoholic, or grandparent migrainous and mother epileptic are two groupings which are most frequently met.

There are still two other groups to be mentioned in passing, the first containing twelve cases and manifesting three defects in the family history, the other group consisting of only two cases and presenting four out of the possible five defects.

Table V gives these fourteen cases in detail and it will be observed that in several cases the same relative has more than one defect, as—mother epileptic and migrainous, father insane and alcoholic. This was true in only a few of the other cases.

From the above table it will be noted that epilepsy as a defective factor occurred in the entire fourteen cases, alcohol in nine cases, insanity and feeble-mindedness in eight cases, and migraine in five cases.

The preceding tables, with the explanatory notes, show in a general way the distribution of the five genetic factors and the frequency with which each one was met, alone and in combination.

I would call your attention to twenty-one cases where one of the grandparents was epileptic. In this group we have the histories of three consecutive generations to study. The first (grandparents) and the third (patient) we know to be epileptic, while the second genera-

TABLE V.—CASES SHOWING MORE THAN TWO HEREDITARY DEFECTS IN ANCESTRY.

tion (representing the parents of patient) gave the following history: In seven cases the epilepsy continued through the three generations; in three instances it was replaced by migraine in the second generation only to make its appearance in its old form in the patient; in the remaining eleven cases there was nothing unusual noted with reference to the mental instability of the individual. This latter group forms a very interesting series of cases inasmuch as each case represented the offspring of an epileptic parent and the parent of an epileptic offspring, yet was without any mental symptoms.

This is a representative group of recessive epilepsy showing that defective germ-plasm may lie dormant for a generation awaiting some environmental condition to bring it to the surface.

In reviewing the literature on the subject of epilepsy and heredity I found that the age of the onset and its relation to the defects which were inherited from the forebears received but little attention. Donald Gregg of Brookline, Mass., read an excellent contribution to the subject of the potency of hereditary factors before the Section on Nervous and Mental Diseases at the meeting of the American Medical Association, June, 1914, the article appearing in the *Journal of the American Medical Association*, November 28, 1914. In his second conclusion he states, "If the age at which symptoms occur among psychoneurotic individuals may be considered an index of the potency of the essential factor at work," etc. Gregg apparently felt some hesitancy in stating that there was a definite relation between the onset age and the potency of the genetic factor. I also wish to be cautious about drawing conclusions that are too dogmatic, for it will doubtless be necessary to make numerous alterations in our present data and study a vast amount more material before any definite conclusions can be drawn from a subject so broad.

I have computed, under several of the different divisions into which I have divided this series, the age at which the epilepsy was first noted. (That usually means the age of the first convulsion).

The first group considered was that made up of the ninety-six cases showing but one of the five hereditary defects.

HEREDITARY FACTOR.

	Average Age at Onset.
Feeble-mindedness	6.2 years
Migraine	8.5 "
Epilepsy	11.1 "
Alcohol	13.7 "
Insanity	16.0 "

From this same group the average age at onset of the epilepsy was determined with reference to which one of the parents, or whether both had the defect, but without regard to what the defect might be.

ANY ONE OF THE FIVE DEFECTS.

	Average Age at Onset.
Mother	9.8 years
Father	12.1 "
Both parents	5.0 "

The next computation takes into consideration the number of defects inherited by the patient (Table II) and concludes the entire series.

NUMBER OF DEFECTS.

	Average Age at Onset.
One defect	11.1 years
Two defects	11.3 "
Three defects	11.6 "
Four defects	6.5 "

The age at onset with reference as to whether the heredity was direct or collateral was also computed, showing that those cases in the former class had an earlier onset than those in the latter.

Epilepsy	Direct	9.4 years
"	Collateral	13.0 "
Insanity	Direct	10.6 "
"	Collateral	14.6 "
Feeble-mindedness	Direct	7.5 "
"	Collateral	16.0 "

The average age of the onset of the epilepsy when computed with reference to the hereditary factor alone fluctuated between 6.2 years for feeble-mindedness to 16 years for insanity, while, when considered with reference as to which parent or whether both parents were defective, but with regard for the particular defect, the age at onset varied from 5 years where both parents were defective to 12.1 years where the father transmitted the defect.

I have constructed a chart to represent graphically the difference in the age of the onset of the epilepsy when both the defect and the parent possessing it are considered. The upper curve is the father's, the middle curve the mother's, and the lower curve represents the situation where both parents are defective. The outside vertical line indicates the onset age, while the five genetic factors are placed on the horizontal line above.

Granting for the present that the data so far submitted are inadequate to substantiate the theory that there is a definite relation between the age at onset of the epilepsy and the potency of the factor, but rather leads us to believe that the potency of the factor is dependent more upon its source, that is, whether maternal or paternal, and being decidedly more "virulent," if I may use the term, in those cases where both parents have the same defect, yet, I am still inclined to believe that between the age of onset and the hereditary factor there is a relation which depends, first, upon the potency of the factor, and second, upon the environmental conditions. How definite this relation may be one can say only after studying the cases sufficient in number and

SUMMARY OF TABLE VI.

HEREDITARY FACTOR.

Epilepsy	5.3
Alcohol	10.2
Insanity	14.1
Migraine	6.2
Feeble-mindedness	5.3
Alcohol	16.6

BOTH PARENTS.

Collateral	9.0
No cases	9.0

MOTHER.

Collateral	10.2
No cases	14.1

FATHER.

Collateral	14.1
No cases	16.6

the onset was at an earlier date than in those cases where only one parent was defective.

5. There was practically no difference between the average age at onset in those cases inheriting two or three defects and in those cases where the family history revealed but one.

6. Those cases with direct heredity averaged an earlier onset than those cases with collateral heredity.

7. The average age at onset in one hundred and fifty-seven cases with heredity was a little over eight years younger than two hundred and five cases computed without reference to heredity.

8. Thirty-nine percent of the entire group had more than one hereditary defect in the family history.

9. Eighty percent of the cases had direct heredity, and fifty-eight percent of the entire group gave a history of epilepsy in some member of the family.

10. Eleven cases, the offspring of epileptic parents and the parents of an epileptic offspring were free from mental defects themselves. I shall not discuss what I believe the errors to be in the above suggestions, some of them which are apparently obvious may prove, on further investigation, that they approach much nearer the actual conditions than we have heretofore believed.

detail from which conclusions may be drawn which are worthy of consideration.

I hardly feel justified in stating that conclusions of a definite nature have been drawn from this study; rather would I say, in closing, that the following suggestions have presented themselves from the above work. These conclusions or suggestions, as I prefer to call them for the present, are based upon the study of one hundred and fifty-seven cases from the Monson State Hospital, seventy-five females and eighty-two males, including practically all the hereditary cases of epilepsy which have been admitted to the hospital where complete family histories were available.

1. Epilepsy, alcohol, insanity, migraine and feeble-mindedness are named in the order of the frequency with which each factor was met.
2. Named in the order of their potency in the production of an early onset of the epilepsy in the offspring, feeble-mindedness came first, followed by migraine, epilepsy, alcohol, and insanity.
3. With the exception of alcoholism all the maternal defective factors were manifested in the offspring at an earlier date in the form of epilepsy than those factors transmitted by the father.
4. When both parents had the same defect

STUDY OF A CASE OF EPIDEMIC TYPHUS FEVER IMPORTED INTO CENTRAL NEW YORK.

By I. H. LEVY, M.D., SYRACUSE, N. Y.,

AND

J. L. KANTOR, M.D., SYRACUSE, N. Y.

On the evening of April 12, 1915, there was admitted to the Hospital of the Good Shepherd, Syracuse, a Macedonian immigrant, 42 years old, suffering from fever and a profuse rash. The next day he was transferred to the City Hospital, where we had the opportunity of following him to convalescence. According to the history subsequently obtained, he had but recently arrived in this country, had been well until April 7, when he began to experience malaise and loss of appetite. Two days later (April 9) he suddenly came down with a chill, severe headache, fever, and a dry cough. There was no expectoration or vomiting, and no rash was observed by the patient or his friends. On his admission to the hospital on the fourth day of his illness, he complained of frontal headache and of myalgic pains, especially in both thighs. There was no pediculosis capitis, pubis, or vestimenti.

Physical examination revealed the following:—

The patient was a well built, very dark skinned, middle-aged man, and appeared rather severely prostrated. He understood but little English, and even when spoken to in his own language (Bulgarian) seemed inattentive and confused. He was observed

to scowl occasionally and to put his hand to his head. The conjunctivae were markedly suffused and presented distinct petechial extravasations, five in the right, and one in the left lower fold. Photophobia, however, was not present. The pupils were contracted but otherwise normal. The tongue was thick, glazed, and fissured; the teeth were covered with sordes; the throat was dry and red. There was marked hypersensitiveness at Libman's test point (styloid process). The neck was held rather rigid, apparently to prevent movements of the head. At any rate there were no unequivocal signs of meningeal irritation—no tache, Kernig, Brudzinski, or Babinski. The knee-jerks were not elicited.

The patient coughed occasionally without bringing up sputum. The respirations were accelerated (34 to the minute) but save for some scattered rhonchi, the lungs were negative. The heart borders were normal, the action rapid, and the sounds of poor quality; no murmurs were audible. The pulse was full and dicrotic. The sharp edge of the spleen could be felt 3 c.m. below the costal margin.

The skin showed a remarkably profuse, blotchy,

eruption, universally distributed except on the face and genitals. The rash was distinctly visible on the dorsum of the hands and feet; it was most marked on the shoulders and abdomen. The lesions consisted of dirty pink macules and purplish petechiae, with indistinct borders fading irregularly into the surrounding skin. Especially common was a large macule with a petechial center. There was no herpes.

Course. The patient gradually became more prostrated and delirious. He mumbled to himself and on several occasions tried to get out of bed. There was involuntary urination and defecation. The pulse increased in rate, reaching 132 on the 15th of April. The cough became more frequent and moist râles developed at both bases; the respiration reached 44 on April 16, when the patient developed a transient hoarseness. At this point the rash began to fade perceptibly. The next day he seemed brighter.

On April 18 (tenth day of the disease), the temperature, which had heretofore remained practically constant between 103.6 and 104, and which had not responded to sponging, suddenly fell to 100.2. It rose in the afternoon, vacillated somewhat the next

FIG. 1.

Temperature, Pulse, Respiration, and Blood Pressure in a Case of Typhus Fever.

The above is a modified Janeway blood-pressure and pulse chart. The uppermost (solid) curve represents the temperature, the second (dotted) curve the pulse, the third (cross-hatched) curve the systolic pressure, the fourth (dotted and cross hatched) curve the diastolic pressure, and the lowermost (solid) curve the respirations. The uppermost heavy horizontal line (at "120") represents the "normal" temperature and systolic blood-pressure, the middle heavy horizontal line (at "80") gives the "normal" pulse rate and diastolic blood-pressure, whereas the lowermost heavy horizontal line (at "20") indicates the "normal" respiration rate.

two days, and then remained at normal. On the first day of defervescence the patient was put on stimulation (whisky and digitalis), which was continued for four days. Even before the drop in temperature the pulse became perceptibly slower. On the 19th, irregularities due to premature contractions were observed; on the 24th, diastolic murmurs could no longer be made out; and on the 25th, the premature contractions ceased. The following day the lungs were found clear of râles. On April 30, the day of his discharge, a short systolic murmur was heard at the apex for the first time. The spleen was still palpable just below the costal margin, the skin showed a few fading spots (there was no desquamation), the eyes were clear.

CLINICAL OBSERVATIONS.

Blood Pressure. Although it is well known that typhus, like typhoid, is a low blood-pressure disease, studies of this feature have apparently not been recorded in the literature. A chart of the systolic and diastolic blood pressure in our case is presented herewith (Fig. 1). The observations were made with a "Tyco" instrument at 10 o'clock each morning. The diastolic readings were taken by the auscultatory method. A study of the chart seems to bring out the following points:—

(1) The diastolic blood pressure varied directly with the temperature and pulse rate, and appeared to be a more accurate guide to the general condition of the patient than the systolic pressure. The lowest diastolic reading (54) was obtained on the eleventh day, in the midst of the "crisis" and at a time when the heart first showed signs of weakness. The diastolic pressure reached "normal" on the first day of defervescence. (2) The lowest pulse pressure was recorded on the first day of defervescence. (3) The systolic pressure rose relatively slowly after the crisis and did not reach "normal" until the ninth day of defervescence.

If we regard the diastolic pressure as "an indicator of the amount of peripheral resistance

present in the arterial system" and the systolic as "an indicator of the force of the ventricular contraction of the heart" (Nicholson¹), the conclusion is suggested that the restoration of normal arterial tone is one of the immediate accompaniments of crisis—as is the resumption of normal temperature and pulse rate—whereas the full heart power is completely recuperated only at a distinctly later period. Of course further studies of this point should be made before definite conclusions are drawn.

The Blood Picture. Rabinowitsch² was apparently the first to point out that in the early stages of typhus there is an increase in the large mononuclear cells (similar to the "irritation forms" of Türk) and that these cells disappear from the circulating blood just before the crisis. He observed this phenomenon in 98 of 125 cases. Wikler³ mentions that an increase in the large mononuclears is an invariable accompaniment of experimental typhus in monkeys. The observations in our case seem to be in accord with these findings. The examinations were made each morning at ten o'clock, and from 200 to 400 cells were counted at each sitting. As indicated in the accompanying table (Fig. 2), the large mononuclears appeared in excess during the height of the disease, disappeared on the day preceding the "crisis," showed a transient rise on the last day of the "crisis,"* and then dropped to normal limits during convalescence. This peculiar behavior of the leucocytes seems to be a fourth specific phenomenon associated with defervescence in typhus fever. The total number of white cells did not reach normal until the fourth day of normal temperature.

Hemoglobin estimations, made on the twelfth, thirteenth, and fourteenth days, varied between 90 and 95% (Sahli). The red cells at that time ran between 4,200,000 and 4,550,000. Unfortunately, no erythrocyte counts were made during

* The term "crisis" refers to the entire period of rapid defervescence.

the acute period of the disease, but appreciable anaemia was certainly never present. In view of the above findings, it is hard to accept Rabinowitsch's belief that the poison of typhus fever is essentially hemolytic in nature.

The Urine. This is said to be diminished in amount and increased in specific gravity except just before the crisis, when many authors describe a transient diuresis as a not uncommon occurrence (Murchison,⁴ Curschmann⁵). Our patient voided freely throughout the entire illness, and although complete twenty-four hour specimens were not always obtained, it is safe to estimate the average daily excretion at from one and a half to two liters. The specific gravity varied between 1005 and 1015. The fluid intake was forced from the beginning.

There was a rather marked febrile albuminuria and cylindruria, and even a month after defervescence a few hyaline casts and a trace of albumen were demonstrable. Our records showed an apparent increase in acidity (to phenolphthalein) and in specific gravity, beginning the day before the crisis and continuing a week after defervescence. Unfortunately we were unable to follow the urea excretion during the illness. This is especially to be regretted as there is serious disagreement as to its behavior in typhus. Thus the older writers (cited by Murchison) speak of a decided increase in the urea output, whereas Curschmann insists that this is not often the case and that the excretion is even diminished. A retention of chlorides is constant.

In our case the diazo was positive as long as the fever lasted. Tests for bile, sugar, acetone, and diacetic acid were constantly negative. Rabinowitsch⁶ found nobilin increased in 74% of his cases. The test, performed according to his directions, was repeatedly negative in our hands.

Complement-fixation and agglutination tests have been used of late in the study of typhus fever. In the series of cases forming the basis of the recent important contribution of Plotz, Olitsky and Baehr,⁷ 71.8 per cent. gave a positive complement-fixation test, and 92.1 per cent. gave a positive agglutination test in the post-critical stage of the disease. In our case the former reaction was negative, but the latter was strongly positive (1:1800).

We wish to express our thanks to Dr. Plotz for his studies on the blood-serum of our case; also to Dr. F. W. Sears, Health Officer of Syracuse; and to Dr. F. C. Burrows, physician to the City Hospital, for their courtesy in turning the case over to us for study.

BLOOD-PRESSURE.

By CADIS PHIPPS, M.D., BOSTON.

Second Assistant Physician, Boston City Hospital.
(Third Medical Service.)

A LIST of figures denoting the blood-pressure determined in different parts of the body would at first thought seem uninteresting. However, when we stop to consider the importance placed upon an individual's blood pressure in regard to diagnosis, prognosis, and treatment, and the narrow limits observed in examination for life insurance (120 mm. to 140 mm. for a man and 110 mm. to 130 mm. for a woman), it is of value to know how great may be the variations in the same individual.

In brief, blood-pressure depends upon the energy of the heart, the peripheral resistance, and, to a lesser degree, the volume of blood. That a certain minimum pressure (diastolic) is maintained depends upon this peripheral resistance of arterioles and capillaries and also the elasticity of the vessel walls. Friction also plays a part,—not so much friction of the blood with vessel walls, for the blood directly in contact with them is almost stationary, but rather the friction within the circulating fluid itself which, of course, varies directly with the viscosity. (Poiseuille¹ has formulated a law explaining this).

However, there arises the question of what factors may enter into the production of blood-pressure as we ordinarily determine it, and if these conditions, unless recognized, may not be a source of error. There are certain physiological variations such as those caused by posture, emotion, digestion, exercise, etc.

For example, we know that blood-pressure becomes higher upon a patient's arising from a recumbent position. If, however, the individual is markedly fatigued, the pressure may fall 10 or 20 mm. It has also been noted that "neurasthenics" show this fall instead of the expected rise.

Emotion may raise the blood-pressure. Probably many of us have noticed that a blood-pressure which we have taken previously will have risen 20 or even 30 mm. when determined in the presence of a class of students, and the same individual's blood-pressure will return to the first height observed shortly after the excitement of the clinic has passed.

Being curious to determine if possible whether or not the location of the artery upon which pressure is applied and the thickness of the over-

(With the exception of Cases 1, 2, 12, 15, 26, 30, and 33 the acute symptoms had disappeared and the patients were ready for discharge.)

lying tissues might influence the readings, I have tried fastening the cuff about each arm (our usual method) and also about each thigh and calf, determining the pressure in these latter instances by the cessation of the pulsation in the Dorsalis Pedis artery. I have used a "Tycoos" sphygmomanometer, verifying the results frequently with a mercury manometer, both of them having a rubber cuff 12 cm. in width. My usual method was to have one of my house-physicians take the reading at a signal from me, repeating this until I had three practically identical readings, or else to take the pressure himself and compare his findings with mine afterward. In this way I hoped to avoid personal error. In each instance the patient was recumbent. I avoided cases having such local conditions as injury to the extremities, oedema, etc., which might prove a source of error, but on the other hand I have been quite uninfluenced by blood-pressure findings, in my selection, having included, for the sake of completeness, three cases in which I was unable to palpate the Dorsalis Pedis artery in one foot and one case where I could not feel it in either.

CASES.

Of the thirty-six cases observed, there was only one (No. 13) in which the pressure was everywhere practically the same.

In thirty-three instances there was a difference of 5 mm. or more in the brachial pressure as determined by palpation compared with the auscultatory reading, eighteen readings showing a higher pressure by palpation and fifteen the contrary. In four cases the variation was as great as 10 mm.

The right and left arms showed a difference in pressure, apparently, of 10 mm. or more in 20% of the cases, with no tendency for it to be uniformly higher in either arm. It is of particular interest to note here that in Case No. 36 (aortic aneurysm, verified by x-ray) the difference in pressure was 20 mm., whereas in Case No. 12 (cirrhosis of the liver with no pathological condition of the heart and only slight arterio-sclerosis, as shown by autopsy), the variation was 30 mm.

The variations between pressures obtained by applying the cuff on the arms, thighs, and calves, and between the right and left thighs, and the right and left calves, were even more marked. The results are almost impossible to classify as the variations range from 5 or 10 mm. to over 60 mm. In general, it may be said that the pressures obtained in the arms are lower than those obtained in the thighs or calves, although in Case No. 12 the pressure in the arm was 30 mm. higher than that obtained in the calf.

To get further evidence of the influence on the blood-pressure reading of the tissues overlying the artery, I placed a strip of fatty meat, about 10 cm. wide and 2 cm. in thickness, loosely

about the arm under the cuff on two normal young adults. It caused no variation from the reading which I obtained on the bare arm. Placing a small roll of meat along the edge of the biceps gave me a reading of about 10 mm. lower. The same results were obtained by using folds of gauze.

During these observations I have noticed, furthermore, that if the patient raised his head the pressure rose 5 to 10 mm. A single vigorous cough made the needle fluctuate 10 to 20 points upward, and, what was more interesting to me, even cases where the patient's pressure was as low as 130 mm., if the pressure in the cuff were increased to even 200 mm., a vigorous cough would cause the needle to move and also a distinctly audible and palpable pulse-beat would be transmitted.

SUMMARY.

1. A difference of 5 or 10 mm. in the blood-pressure reading may be observed, dependent on whether the pressure be determined by palpation or auscultation, but neither method can be said to be the more accurate.

2. The blood-pressure reading may vary in the same individual between the right and the left arms, thighs, or calves, or between arm and thigh and calf; this variation is in no way uniform.

3. The variations are apparently as great in young individuals as in old, and in cases showing healthy arterial walls as where there is arterio-sclerosis.

4. The location of the artery, especially in its relation to other structures such as bone and muscle, probably is of much greater importance in determining the blood-pressure reading than is thickness of the overlying tissues.

5. Difference between the right and left brachial pressures is by no means diagnostic of aortic aneurysm.

6. The presence of a higher pressure in the leg than in the arm is not diagnostic of aortic insufficiency, although this has been stated by previous observers. (Leonard Hill, "Heart," 1910, i, p. 73, and Humphrey Rolleston, "Heart," 1912, iv, p. 83).

7. Blood-pressure in the vessels of the leg and arm is *not* "practically the same" ("Blood-Pressure," Edward H. Goodman, 1914, p. 89) in normal individuals."

SAMUEL JOHNSON AND DR. THOMAS LAWRENCE.

OF the various physicians with whom Samuel Johnson at various times of his life came into contact there was none with whom his friendship was more intimate than with Dr. Thomas Lawrence, whose name appears frequently in Johnson's correspondence and in the pages of Boswell. Dr. Lawrence was not only one of the most eminent physicians of his time but was a man of culture, a profound Latin scholar, and gifted with a degree of literary taste and insight which made it possible for Johnson to meet him upon more than a professional basis.

It is interesting that this Dr. Lawrence was a descendant of the Lawrence who was an intimate friend of John Milton, and to whom the latter addressed his famous tenth sonnet beginning,

"Lawrence, of virtuous father virtuous son."

This virtuous father was Henry Lawrence, member for Herefordshire in the Little Parlia-

ment of 1653; president of Oliver Cromwell's council; high in favor with Richard Cromwell; and author of "Our Communion and War with Angels" (published in 1646). Of the virtuous son, Milton's friend, little is known.

Dr. Thomas Lawrence, their descendant, was born in 1721. The essential facts of his life are to be found in dictionaries of medical biography. His first acquaintance with Johnson seems to have begun about 1754; for in a memorandum of that date Johnson mentions him among a list of forty persons whom he visited. The correspondence between the two, however, forming our chief knowledge of their relations, did not begin until some years later. In 1758 Johnson mentions Dr. Lawrence in a letter to Mr. Langton; and again in one of his letters to Mrs. Thrale he refers to Lawrence as saying that medical treatises should always be in Latin. Lawrence's letters to Johnson were written in that language. Finally under date of February 7, 1775, appears Johnson's first letter to "the learned and worthy Dr. Lawrence whom Dr. Johnson respected and loved as his physician and friend."

"Sir:—One of the Scotch physicians is now prosecuting a corporation that in some public instrument have styled him *doctor of medicine* instead of *physician*. Boswell desires, being advocate for the corporation, to know whether *doctor of medicine* is not a legitimate title, and whether it may be considered as a disadvantageous distinction. I am to write to night; be pleased to tell me. I am, Sir, your most, etc.,

"Sam. Johnson."

As time went on, Johnson's regard for Lawrence evidently increased. In one of his conversations in 1776 he said, "My knowledge of physick I learnt from Dr. James, whom I helped in writing the proposals for his dictionary, and also a little in the dictionary itself. I also learnt from Dr. Lawrence, but was then grown more stubborn." In January, 1777, Johnson first consulted Dr. Lawrence professionally. He had been suffering for some days from dyspnea and says in a letter to Mrs. Thrale under date of January 15, "I found it now time to do something, and went to Dr. Lawrence, and told him I would do what he should order without reading the prescription. He sent for a chirurgeon and took about twelve ounces of blood, and in the afternoon I got sleep in a chair.

"At night, when I came to lie down, after trial of an hour or two, I found sleep impractic-

cable, and therefore did what the doctor permitted in a case of distress. I rose, and opening the orifice, let out ten ounces more. Frank and I were awkward; but with Mr. Levett's help, we stopped the stream, and I lay down again, though to little purpose; the difficulty of breathing allowed no rest. I slept again in the daytime in an erect posture. The doctor has ordered me a second bleeding, which I hope will set my breath at liberty. Last night I could lie but a little at a time."

As years progressed Johnson's health grew steadily worse and the references to it in his letters became more and more frequent. His own sufferings, however, did not prevent him from sympathizing with those of his friends. In a letter to Lawrence under date of January 20, 1780, he begins with an account of his own illness: "I have been hindered by a vexatious and incessant cough, for which within these ten days I have been bled once, fasted four times, taken physie five times, and opiates, I think, six. This day it seems to remit." Following this, however, he proceeds with a most feeling and sympathetic address to his friend upon the recent loss of the latter's wife.

In a letter from London to Mrs. Porter, under date of April 8, 1780, Johnson says, "I have lately had colds; the first was pretty bad, with a very troublesome and frequent cough; but by bleeding and physie it was sent away. I have a cold now but not bad enough for bleeding." Bleeding and physie were the panaceas of the age. It is small wonder that people dreaded to visit the physician almost as much as the surgeon,—a dread whose inheritance is probably responsible for the failure of timely consultation even in the present day. In spite of all, Johnson's health seems even to have improved during the succeeding months, and on June 18, he says, "In the morning of this day I perceived a remission of those convulsions in my breast which had distressed me for more than twenty years." Lawrence himself was failing at this time and had grown exceedingly deaf, an infirmity to which Johnson makes reference in various letters to others. On March 19, 1782, Johnson wrote in his *Prayers and Meditations*, "Poor Lawrence has almost lost the sense of hearing; and I have lost the conversation of a learned, intelligent, and communicative companion, and a friend whom long familiarity has much endeared. Lawrence is one of the best men whom I have known." Croker quotes a rather pathetic

incident of a conversation between the two, struggling with their respective infirmities. Dr. Johnson was exceedingly ill and Mrs. Thrale accompanied him to consult Dr. Lawrence at the latter's office on Essex street. "The physician was, however, in some respects more to be pitied than the patient. Johnson was panting under asthma and dropsy; but Lawrence had been brought home that very morning struck with a palsy from which he had strove to awaken himself by blisters: they were both deaf and scarce able to speak, one from difficulty of breathing, the other from paralytic debility. To give and receive medical counsel, therefore, they sat down on each side of a table in the doctor's gloomy apartment, adorned with skeletons, and wrote questions and answers to each other in Latin." In May, 1782, Johnson again sent to Lawrence a brief Latin note descriptive of his symptoms:

"*Maiis Calendis, 1782.*

"*Novum frigus, nova tussis, nova spirandi difficultas, novam sanguinis missionem suadent, quam tamen te inconsulto nolim fieri. Ad te venire vix possum, nec est eur ad me venias. Licere vel non licere uno verbo dicendum est; caetera mihi et Holdero* reliqueris. Si per te licet, imperatur nuncio Holderum ad me deducere. Postquam tu discesseris quò me vertam?"*

Though Dr. Lawrence made slight recovery from his paralytic shock, his health continued steadily to fail and he died on June 13, 1783. His son, the Rev. John Lawrence, died two days later. It was upon an earlier illness of this son that Johnson had written his Latin ode, "Ad Thomam Lawrence," (1, 180). On June 17, Johnson writes in a letter to Taylor, "It has pleased God, by a paralytic stroke in the night, to deprive me of speech. I am very desirous of Dr. Heberden's assistance, as I think my case is not past remedy." Later in a letter to Mrs. Thrale he refers feelingly to the death of Lawrence. Apparently for a year or two, on account of Lawrence's failing health, he had begun to depend medically upon Dr. Heberden and Dr. Pepys.

The story of Johnson's last illness and of his death, on December 13, 1784, is written at length in the pages of Boswell. It is interesting to know that there has recently been brought to this country a collection of eleven of the autograph letters of Johnson to Lawrence, as well as the original manuscript of the Latin ode. Only one of these letters, that quoted above, is included in Boswell's *Life*. The remaining ten

* Johnson's apothecary in the Strand.

are still unpublished and eight of them deal with Johnson's state of health.

The relations of great men, whether men of letters or of affairs, with their physicians are, perhaps, no different in kind from those of more ordinary patients: yet they seem often to acquire, especially for members of the profession, a peculiar interest dependent not only upon the distinction of the patient, but upon the character of his consultant and adviser as well. Dr. Lawrence was a man of as great distinction in his own profession, and as truly a representative of the age, as was Johnson himself; and the record of their association, both social and professional, during so many years, has fortunately persisted through their letters and through the diligence of Boswell, their common biographer.

HAVELOCK ELLIS AND BIRTH CONTROL.

IN the September issue of *Physical Culture*, Mr. Havelock Ellis, the distinguished British sociologist and scientific writer on eugenic subjects, presents the first of a projected series of three articles on birth control. It is probably ill to differ with one of his world-recognized authority, yet there seem certain points in which, perhaps, at least in this preliminary article, he errs in his interpretation of admitted facts.

The burden of Mr. Ellis's contention appears to be that because lower forms of life, like the herring, are profusely prolific, whereas higher forms, like the elephant, reproduce themselves very slowly, therefore to reduce the birth-rate in man is to improve the type and accelerate evolution. As evidence of this he adduces Spencer's theory of the function of sex in evolution, which Prof. Coulter has expressed as "reproduction under peculiar difficulties."

....."The object of sex is by no means to aid reproduction, but, rather, to subordinate and check reproduction in order to evolve higher and more complex beings. Here we come to the great principle, which Herbert Spencer developed at length in his 'Principles of Biology,' that, as he put it, Individuation and Genesis vary inversely, whence it follows that advancing evolution must be accompanied by declining fertility. Individuation, which means complexity of structure, has advanced as Genesis, the unrestricted tendency to mere multiplication, has receded. This involves a vastly diminished number of offspring, but an immensely increased amount of time and care in the creation and

breeding of each; it involves also that the reproductive life of the organism is shortened and more or less confined to special periods; it begins much later, and usually ends earlier, and even in its period of activity it tends to fall into cycles. Nature, we see, who at the outset had endowed her children so lavishly with the aptitude for multiplication, grown wiser now, expends her fertile imagination in devising preventive checks on reproduction for her children's use.

"The result is that though reproduction is greatly slackened, evolution is greatly accelerated. The significance of sex, as Coulter puts it, 'lies in the fact that it makes organic evolution more rapid and far more varied.' It is scarcely necessary to emphasize that a highly important, and, indeed, essential aspect of this greater individuation is a higher survival value. The more complex and better equipped creature can meet and subdue difficulties and dangers to which the more lowly organized creature that came before—produced wholesale in a way which Nature now seems to look back on as cheap and nasty—succumbed helplessly without an effort. The idea of economy begins to assert itself in the world. It became clear in the course of evolution that it is better to produce really good and highly efficient organisms, at whatever cost, than to be content with cheap production on a wholesale scale. They allowed greater developmental progress to be made, and they lasted better. Even before man began, it was proved in the animal world that the death-rate falls as the birth-rate falls."

These statements are doubtless all true, but the inference which Mr. Ellis seems to draw from them is that to reduce the birth-rate is necessarily to improve environment and increase the good quality of the stock.

....."To improve the environment is to check reproduction, being indeed the one and only fundamental way in which undue reproduction can be checked. That may be said to be an aspect of the opposition between Genesis and Individuation, on which Herbert Spencer insisted, for by improving the environment we necessarily improve the individual who is rooted in that environment. It is not, we must remember, a matter of conscious and voluntary action. That is clearly manifest by the fact that it occurs even among the most primitive micro-organisms; when placed under unfavorable conditions as to food and environment they tend to pass into a reproductive phase and by sporulation or otherwise begin to produce new individuals rapidly. It is the same in Man. Improve the environment and reproduction is checked. That is, as Professor Benjamin Moore has said, 'the simple biological reply to good economic conditions.' It is only among the poor, the ignorant and the wretched that reproduction flour-

ishes. Those who desire a high birth-rate are desiring, whether they know it or not, the increase of poverty, ignorance and wretchedness."

The question arises whether possibly Mr. Ellis may not have mistaken effect for cause. No doubt it is true that, within certain limits, birth-rate automatically adjusts itself to conditions; but is it equally true that, within limits, artificial control of birth-rate can regulate conditions? Very likely it can, so long as the race or species practising it does not come into collision with some inimical other race or form of life. But when this does occur, the factor of numbers may well become of decisive importance, and a more prolific, though in some other details inferior, type may outstrip its less fertile, more highly individualized rival. Indeed it seems that even Spencer may have failed to realize that, though individualization is one of the primary methods of evolution, it may be carried on too far and too rapidly and wreck itself by its own momentum. The highly developed type of civilization, which sacrifices the race to the individual, may conceivably be unable, for sheer lack of numbers, to cope with the type of civilization which is willing to sacrifice the individual for the race. It is neither numbers nor high individuation alone which counts, but a combination of the compossible maximum of each.

Life might be far simpler, were a single race of men occupying the world alone, yet this would be undesirable, since it would remove the essential element of conflict. In the long course of evolution, man has triumphed over other forms of life, until only the insects and bacteria remain an important menace. He has not done this, however, by reducing the birth-rate. To-day his chief foes remain they of his own household. The factors which lead to an artificial reduction of birth-rate constitute one of the chief sources of danger to any civilization in the face of another civilization in which these causes have not become so extensively operative.

CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA.

THE sixth annual session of the Clinical Congress of Surgeons of North America is to be held in Boston during the week beginning October 25, 1915, and in general will be conducted in the

same manner as previous sessions. Following the precedent established at London in July, 1914, however, the number in attendance will be limited in accordance with the capacity of the clinics and operating rooms where demonstrations are to be held. A preliminary program for these clinics has already been announced at the leading hospitals of the city. Further details of this program and account of the sessions will appear in subsequent issues of the JOURNAL. The registration for the Boston session is nearly complete and special tickets are soon to be issued. The headquarters of the Congress will be at the Copley-Plaza Hotel.

A series of meetings has been arranged for the first four evenings of the week. At the meeting on Monday evening, October 25, the president elect, Dr. Charles H. Mayo, will deliver his annual address. On each of the three subsequent evenings there will be two meetings, one for the section on general surgery, the other for the section on surgical specialties. The principal papers at these meetings will be read by visiting surgeons and the discussion will be led by Boston surgeons.

It is recognized that the essential part of the meetings of this Congress is the clinical demonstrations, and it is intended that there shall be a complete representation of the clinical facilities of Boston and a demonstration of the work which is being done by its leading general surgeons and specialists. The JOURNAL is glad, through its columns, to extend the courtesy and welcome of the Boston profession to its guests. The success of the Congress will depend upon the energy and cordiality with which every member of that profession does his share in carrying out the careful and thorough plans which have been made by the committee of arrangements for this first meeting of the Clinical Congress of Surgeons of North America in Boston.

MEDICAL NOTES.

NEW YORK DEATH RATE INCREASES.—During the week ended September 11 there were 1355 deaths with a rate of 12.17 per 1,000 of population as compared with 1206 deaths and a rate of 11.27 for the corresponding week of last year. While there were 149 more deaths during the past week, the increase in population accounted for 49. The other 100 were due to increased mortality of certain diseases, particularly measles, scarlet fever, diphtheria, whooping

cough, lobar and bronchial pneumonia and pulmonary tuberculosis.

In spite of last week's jump in the death rate, the rate for the first 37 weeks of 1915 is only 13.54 as compared with 13.97 for the corresponding period of last year.

In view of the loss of population in the City of New York, occasioned by the European war, the Department of Health has felt the need of revising its estimates of the population and has been awaiting the result of the state census, but the Department does not as yet feel justified in accepting as a basis for its calculation, the figures published recently by authority of the Secretary of State. The Registrar has made an estimate of the population, giving weight to the various factors that have been reducing the population during the past year. The revised estimate of the population is 5,597,000. The rate for the past week, based on this revised population, is 12.63.

TYPHOID FEVER IN ILLINOIS.—During the month of August, 1200 cases of typhoid fever were reported in Illinois and at the usual rate it is expected that there will be 3500 cases by the end of September. Extensive anti-typhoid inoculation is advised by the Illinois Board of Health as a check against the spread of this epidemic. The value of such inoculation is already proved beyond question. During the year 1914, there were among the 93,000 troops of the United States only seven cases of typhoid fever. Of these patients four had not been inoculated. The three who had been inoculated had a very mild form of the disease. Of the four not inoculated, all had the disease severely and two died.

PREVALENCE OF MENINGITIS, POLIOMYELITIS, SMALL-POX AND TYPHOID.—The weekly report of the United States Public Health Service for September 3, 1915, notes that during the month of July there were reported 20 cases of cerebrospinal meningitis in New York, and 30 in Virginia. During the same period there were in New York 13 cases of poliomyelitis and 402 of typhoid; and in Virginia, 23 cases of poliomyelitis, 65 of small-pox and 620 of typhoid. There were 86 cases of small-pox in Kansas, 88 in Iowa and 141 in Indiana; and of typhoid there were 125 cases in California, 129 in Kansas, 149 in Indiana and 168 in Texas.

DECLINE IN UNITED STATES IMMIGRATION.—Report from Washington, D.C., on September 9 states that during the year ended June 30, 1915, only 326,700 immigrants came to this country, the lowest number since 1900. The total number of immigrants for the year ended June 30, 1914, was 1,218,480. This decline, which may presumably be attributed in great part to the European war, is regarded by some as an advantageous and by others as a disadvantageous phenomenon.

CARE OF THE TEETH.—A recent study by Bunting and Rickert, members of a research commission of the National Dental Association on the causes of decay of teeth, contains some interesting information regarding the use of tooth powders and tooth pastes. Various proprietary cleaning preparations were tested as to their effect on the enamel of the teeth in conjunction with the action of the saliva. They state that most of the powders on the market are made of chalk, some contain oxide of tin, and pumice stone and cuttle fish form an ingredient of the more gritty pastes. In conclusion the authors state as follows:

"We feel that dentists should make a more close study of the properties of dentifrices which they are prescribing, and also the needs of the mouths in which they are to be used. In cases in which the saliva is viscous and deposits form upon the teeth with great rapidity, making it difficult to keep the mouth clean, then a more abrasive dentifrice might be used to advantage. But when the saliva is thin and the deposits few, an abrasive powder or paste is clearly not indicated. Rather should a fine and hygroscopic preparation be employed which will polish and clean the teeth without wear. The results which we have obtained serve also to call attention again to the importance of brushing the teeth in a vertical rather than a horizontal manner. Especially is this true in the case of sharp preparations, which would have produced no such pronounced results as seen in the experiment had they been brushed lengthwise of the teeth.

PUBLIC HEALTH WORK AT HOME AND ABROAD.—Two publications, one from Scotland and one from Pennsylvania, are full of timely suggestions and recommendations for more efficient public health work. The former is a communication by Dr. William Robertson, health officer of Leith, who, in considering present sanitary conditions of Scotland and England, states that first of all, housing should be bettered. There should not be the opportunity for the unreliable factor to run into another burrow when the one he is living in is demolished for improvements. The segregation of human beings in great masses, under utter lack of hygienic surroundings, cannot fail to be a very important factor in morbidity and mortality.

The public house is the second of the evils which Dr. Robertson would correct. He is not advocating prohibition, but the proper regulation of alcohol. He instances the Germans, from whom, despite public opinion just now, it is possible to learn much. The Germans are very far from abstainers, in fact their capacity for certain alcoholic drinks is a by-word and their consumption of them enormous, but the sensible regulation of drinking robs the public house of its iniquities. Proper legislation on drinks and drinking in England and Scotland would be a benefit to the public health.

Thirdly, in considering his question, Dr. Robertson pointed out the unreasoning nature of the class which he thinks should receive sanitary education in the public schools. After a strike a firm in Leith looked into the improvement in housing of its laborers, eight hundred in number. The increase in wages was 30 per cent, the number of laborers taking advantage of this to improve their housing was two. This is the character of the unthinking, unreasoning personal factor with which health authorities labor.

Dr. Dixon, the health commissioner of Pennsylvania, in a current issue of the publication, "Little Talks on Health," discusses the frequency with which typhoid is contracted by picnic parties who rely on convenient brooks and springs for their drinking water. He urges that vacationists in putting up their lunches for day's trips should always include bottles of drinking water. He urges campers to boil all water used for drinking purposes as well as to discover, if possible, the sources from which their water comes to them.

TUBERCULOSIS WEEK.—In a previous issue of the JOURNAL we have noted from time to time the annual observance of Tuberculosis Sunday. This year the National Association for the Study and Prevention of Tuberculosis has determined to extend this observance over an entire week which is announced for December 6 to 12. Each day of this week will be devoted to a special aspect of the work.

"Medical Examination Day is set for Wednesday, December 8, and will be the first effort on a national scale to urge an annual physical examination for everyone. Plans for the day include an appeal to induce everyone, sick and well, to see a doctor and learn whether they are in good physical condition. The scheme includes also the inauguration on the part of factories, stores and offices of an annual physical examination for all employees. Thousands of anti-tuberculosis associations, other societies and dispensaries all over the country are expected to coöperate in furnishing free examinations for those not able to pay a physician.

Children's Health Crusade Day on Friday, December 10, is planned to interest and instruct school children in healthful living. Special exercises will be held at which lectures, essays, and playlets will be given on the subject of health. This will also be the occasion for launching the Red Cross Christmas seal sale in the schools.

The culmination of the campaign will be the sixth annual celebration of Tuberculosis Sunday. Last year on Tuberculosis Day over 100,000 churches gave attention to the subject of tuberculosis by sermons, talks and announcements. The governors of all the states will be asked to issue proclamations calling attention to the importance of increasing the knowledge of the public on how to avoid consumption. Clubs, lodges and societies will also be asked to consider the

subject at a meeting either on Tuberculosis Sunday or some other day of Tuberculosis Week."

A STUDY OF DIARRHEAL DISEASES AMONG NEW YORK BABIES.—The Bureau of Public Health and Hygiene of the New York Association for Improving the Condition of the Poor has issued a publication entitled "Flies and Diarrheal Disease." It contains a report of three months' study of over a thousand infants in New York on the relation of flies, dirt and artificial feeding and diarrheal diseases. Its conclusions are as follows:

"Almost twice as many infants (1.9) had diarrhea among fly-exposed as among fly-protected infants.

"The group of influences, associated with a dirty home, and designated as the 'dirt' factor, play a similar part in diarrheal incidence among infants. Almost twice as many infants (1.8) had diarrhea in dirty homes as in clean homes.

"Of somewhat greater importance is the influence of artificial feeding. Almost two and one-half times as many infants (2.4) were attacked by diarrhea among the artificially fed as among the breast fed infants. If the milk had not been selected and instruction in feeding given in many cases, this difference would have been still greater.

"The influence of flies and 'dirt' combined is of similar importance to that of artificial feeding. Almost two and a half times as many fly-exposed infants (2.4) in dirty homes were attacked by diarrhea as fly protected infants in clean homes.

"The influence of 'dirt' and artificial feeding combined is still greater. Three and a half times as many artificially fed infants (3.5) in dirty homes were attacked by diarrhea as breast fed infants in clean homes."

AMERICAN PUBLIC HEALTH ASSOCIATION.—At the meeting of the American Public Health Association held in Rochester, N. Y., Edward A. Moree, assistant secretary of the New York State Charities Aid Association, spoke at length on the important part that the daily press has played in promoting public health. In campaigns to reduce infant mortality, in the education of the public in matters of sanitation, milk supply and control of tuberculosis, he regarded the influence of the press as of paramount importance and advocated a campaign of purchased advertising on the evils of patent medicines.

The need for improving rural sanitation was strongly urged by Dr. W. S. Rankin, secretary of the North Carolina state board of health, who pointed out that the field of rural sanitation embraces more than 99% of the area of the United States and more than half of the country's population. He declared that the work of improving rural standards of sanitation should be initiated by the state governments and conducted by the local or county governments.

On September 9, a symposium was held on the death rate of the higher age groups. Dr. Elmer E. Rittenhouse, president of the Life Extension Institute stated that failure to observe the rules of hygiene had increased the death rate from diseases of heart, arteries and kidneys 100% in three decades.

Dr. E. L. Fisk, director of hygiene of the Life Extension Institute, recommended, for the prevention of these diseases, education in safeguarding the circulation and kidneys, and advice against over-strain, over-eating, taking of stimulants and lack of exercise.

Dr. J. F. Anderson, at the same symposium, made the statement that in only 41 cases out of 2,000,000 had vaccination resulted in tetanus.

On "Cancer and the Public Health," Dr. Francis Carter Wood, director of cancer research, Columbia University, declared that comparatively little is known about cancer and there are many problems for the elucidation of which further data are needed, the collection of which would begin at once.

Dr. H. W. Hill, medical health officer of London, Ont., said deaths from cancer were annually increasing, and if they continued would be as numerous by 1925 as those from tuberculosis.

J. Frank Chase of the New England Watch and Ward Society spoke on the suppression of the habit-forming drugs. He stated that there were two factors in the controlling this vice, the demand and the supply. The Harrison Bill attempts almost wholly to regulate the supply for the United States. If the demand is to be checked, addicts must be cured and recruiting of new victims prevented. He therefore urges that, to accomplish this, drug users who are criminals should be segregated, and institutions created for the segregation of drug users who are not criminals, and thirdly, that more careful prescribing on the part of physicians be enforced by more stringent laws and the coöperation of medical societies. The standing committee on habit-forming drugs presented their report. Chief among the committee's recommendations was that a census be made of all habitual users of narcotic drugs; establishment by the states of custodial institutions for non-criminal drug users, and the enactment of laws for more efficient restriction of physicians in prescribing drugs are also recommended.

At the annual election of officers of the Association, the following men were elected: President, Dr. John F. Anderson, director of the hygienic laboratory, Washington, D. C.; first vice president, Dr. George W. Goler, health officer, Rochester; second vice president, Dr. Charles J. Hastings, medical officer of health, Toronto, Ont.; third vice president, Dr. Omar Gillette, Colorado Springs; treasurer, Dr. Lee F. Frankel, Metropolitan Life Insurance Company; secretary, Prof. Selskar M. Gunn, Boston.

Honorary members: Dr. W. S. Gorgas, surgeon general, U. S. Army, Washington, D. C.; Dr. Stephen Smith, state board of charities, New York;

Dr. Frederick Montizambert, director general of public health, Dominion of Canada, Ottawa; and Dr. Henry D. Holton, Brattleboro, Vt. Directors for one, two and three years also were elected.

EUROPEAN WAR NOTES.

CONTINUED INCREASE IN COST OF DRUGS.—In previous issues of the JOURNAL we have, from time to time, noted the progressive increase in the cost of various drugs. During the week ended September 9, there was a further increase of three cents per ounce in the cost of quinine and of \$1.00 a pound in the price of antipyrin. These and other increases are partly genuine on account of interference with the supply and partly due to speculative action on the part of large holders.

EQUIPMENT OF HOSPITAL BY LAVAL UNIVERSITY.—It is announced that the British War Office has accepted an offer from Laval University of Quebec, to establish, equip and maintain for the remainder of the war a stationary hospital of 520 beds in France or wherever else it may be most needed.

BRITISH-ITALIAN AMBULANCE UNIT.—It is announced that a British ambulance unit has recently started for service in Italy. It will consist of twenty motor ambulances, of which sixteen were given by the Red Cross, and of five other motor cars. It will have a personnel of 55 under command of Mr. George Trevelyan, the historian.

AMERICAN SURGICAL UNITS FOR GERMANY.—It is announced that two American surgical units to consist of twenty surgeons and nurses are to be sent from New York under command of Dr. Herman Fischer, of the German Hospital, to Germany and Austria. This expedition is under the auspices of the American physicians' committee and will act in coöperation with the American Red Cross.

DECLINE OF BRITISH AND GERMAN BIRTH RATES.—Report from Amsterdam by way of London on September 12, states that during the month of July, 1915, there were only 2,520 births in Berlin compared with 3,370 in July, 1914. During the quarter ended July 31, 1914, there were in Berlin 10,030 births while during the corresponding quarter in 1915 there were only 7,523.

Statistics recently issued by the British Registrar General indicate that there has been an even greater decline in the growth of population in England and Wales than in Germany.

"The excess of births over deaths in the June quarter was 27,418 below that for the same period of last year.

The excesses for the four last comparative periods are: 1915, 74,515; 1914, 101,933; 1913, 105,727; 1912, 102,293.

The births in England and Wales in the June

quarter, 213,094, make the lowest recorded since the establishment of civil registration. The figures are 12,973 below the same period last year and correspond to an annual rate of 22.9 per thousand or 3.3 below the 10 years' average for the June quarters.

Deaths, totalling 138,579, were the highest for any June quarter in the decade and were 14,445 in excess of June, 1914.

Marriages, probably owing to the war, were 4,390 in excess of last year, at 55,406."

REPORT OF BELGIAN RELIEF COMMISSION.—The New York Belgian Relief Commission has recently issued a report describing its activities during the past ten months. In this time it has distributed food and other relief supplies to the value of more than \$80,000,000. "Up to the first of July, or the end of the first fiscal year of the commission's activities, there were sent to Belgium for the relief of the non-combatant population of the country 305,737 tons of flour, 15,275 tons of rice, 40,680 tons of corn, 15,546 tons of peas and beans, and other supplies, the total weight of which was 423,583 tons.

In addition to the supplies sent to Belgium, the commission has since the first of April last been feeding the destitute people of the German-occupied territory of France. These French sufferers number more than 2,500,000. More than 91,000,000 pounds of supplies have been sent to that part of France. Also about 10,000 tons of food have been donated to relief work in the Grand Duchy of Luxemburg.

The American Red Cross shipped on the Greek liner *Thessalonika* recently for the Red Cross organizations in Turkey and Serbia a consignment of supplies valued at more than \$4,000. Forty-four cases were consigned to Ambassador Morgenthau at Constantinople, and the rest to the various Red Cross organizations in Serbia."

WAR RELIEF FUNDS.—On September 17, the totals of the principal New England relief funds for the European war reached the following amounts:

Belgian Fund	\$277,560.07
St. George's Fund	11,143.36
French Fund	9,430.18
Italian Fund	3,138.10

DISTRIBUTION OF JEWISH RELIEF.—Report from the American Jewish Relief Committee in New York on September 14, states that the total contributions to the Jewish Fund in the United States now amount to \$929,238.38. This sum has been distributed as follows:—

"To Russia, \$455,000; to German Poland, \$195,000; to Austria-Hungary, \$85,000; to Swiss University students, \$2,500; to Jews at Salonica, \$5,000; to Jews at Aleppo, \$2,500; to Jews of Monastir, \$3,000; to Jews of Gallipoli and Dardanelles, \$2,500; to Rabbi Meir for relief in Uskub and Ischtip, \$1,000; to Palestine, \$25,000;

for stocking Vulcan with foodstuffs, medicines, etc., \$4,627.81; administration expenses for offices of treasurer, secretary and propaganda committees, \$12,470.47; balance on hand, \$55,640.10.

BOSTON AND NEW ENGLAND.

HAYMARKET SQUARE RELIEF STATION.—It is reported that during the first eight months of the current year, 3000 fewer accident cases have been treated at the Haymarket Relief Station in Boston, than during the corresponding period in 1914. This is the first time for nine years that the number of cases has not increased at a steady annual rate of about 5%. The exact cause of this decline is hardly certain. It may be attributable in part to the decline of immigration since the outbreak of the war, and to the operation of the workmen's compensation law.

BOSTON HEALTH COMMISSION.—Dr. Francis X. Mahoney, the new health commissioner of Boston has finally announced the appointment of the deputy commissioners in charge of the various divisions of the department. Dr. Thomas B. Shay is to have charge of the medical division, Dr. Patrick H. Mulowney of the food division, Dr. William H. Davis of the vital statistic division, Mr. Thomas Jordan of the sanitary division and Dr. Francis H. Slack of the bacteriological laboratory.

SCARLET FEVER IN WAKEFIELD, MASS.—The public schools of Wakefield, Mass., have been ordered closed to prevent an epidemic of scarlet fever. Four cases have already developed and as about 500 children have been exposed to the disease, more attacks are feared. The exposure occurred when a boy with scarlet fever attended the Labor Day performance of a local moving picture theatre. The theatre has been fumigated and ordered to remain empty for a week.

THE SPREAD OF PELLAGRA.—The State Department of Health reports in its monthly bulletin for August, 1915, the spread of pellagra in this state. It states that while in 1910 there was but one death from the disease in Massachusetts, during 1914 there were 18. In the year 1913 there were 1013 cases reported. The spread of the disease to all sections of the United States is a matter of grave concern.

NEW HOSPITAL AT MARSHFIELD HILLS, MASS.—It is announced that a small general hospital erected in Marshfield Hills, Mass., for the benefit of the South Shore district between Quine and Plymouth, will be ready for occupancy in about one month. It will consist of 33 beds sixteen for surgical cases, eleven for medical and six for obstetrical cases.

HOSPITAL BEQUESTS.—The will of the late Grace Parkman of Dorchester, Mass., which was filed in the Suffolk Registry of Probate on Sep

ember 8, contained bequests of \$3000 each to the Dorchester Home for Consumptives and to the Boston Children's Hospital. A second will, however, which was later found and filed, differs materially from the first and it is as yet uncertain how these legacies will be awarded.

HOSPITAL REQUIREMENTS AT PENIKESSE ISLAND.—The recently published report of the State Board of Charity for the year ending November 30, 1914, records the progress in the care of patients at the Penikese Hospital, Penikese Island, where were at the close of the year ten patients remaining at the hospital, one patient having died and one being released. As has been previously pointed out in this JOURNAL, the present equipment of the Penikese Hospital is incapable of affording patients proper hospital care or of safeguarding nurses and attendants from undue exposure to contagion while performing their duties. The Board has again requested, therefore, that a modern hospital and dispensary building be erected for the proper care of these patients, and asks an appropriation of \$40,000 for this purpose.

APPOINTMENT OF DIRECTOR OF SCHOOL PHYSICIANS.—At a meeting of the school committee of Boston on September 9, Dr. William H. Devine of South Boston was appointed director of school physicians. This is a new office, created since the resignation of Dr. Harrington as director of school hygiene and made necessary because of the increase in the staff of school physicians. The details of this division of office appeared in the previous issue of the JOURNAL. Dr. Devine will have charge of forty physicians who will be chosen by civil service examination to be held in month, and of 46 nurses who are now in the service.

REUNION OF MASSACHUSETTS GENERAL HOSPITAL NURSES.—The annual meeting and reunion of the alumnae of the Massachusetts General Hospital Training School for Nurses was held at that institution on Monday and Tuesday of last week, September 13 and 14. At the sessions Tuesday, Dr. William H. Smith read a paper "New Methods of Medical Treatment," and Dr. Frederick A. Washburn, the administrator, gave an address on the history of the hospital. It is announced that graduate nurses of the Massachusetts General Hospital have given \$1000 for the equipment of the Massachusetts Nurses' Association at the Belgian-American Hospital. The alumnae organization consists of 465 members and this reunion is the largest of its kind to be held by the association. Members came from various parts of New England, New York State and Canada.

The desirability of providing the association with an endowment was discussed, and the hope expressed that in eight years, at the time of the twentieth anniversary of the training school, an endowment fund of \$250,000 can be turned over

to the trustees of the hospital, thereby providing adequate support for the training school and releasing the funds of the hospital used for that purpose, for other needed work.

MEASLES IN NANTUCKET.—In the current issue (August, 1915) of the monthly bulletin of the Massachusetts Health Commission is an account of the recent epidemic of measles in the island of Nantucket. Prior to May 7, 1915, only eight cases of measles had ever been reported in Nantucket, four in 1910 and four in 1911. During the present summer, however, 111 cases have occurred. The epidemic is thus described in part by Dr. Adam S. MacKnight, the local health officer:

"It is reasonably safe to assume that the Nantucket epidemic of measles has run its course, and, fortunately, indeed, with but one immediate fatality. Up to the present time the epidemic has not resulted in the development of any secondary foci of this disease among the children of visiting families, which, of course, was to be looked for.

"This epidemic, however, shows the silliness of failure to consult physicians in the early stages of measles, which are more likely to prove infectious than the later stages; the folly of indifferent nursing, lack of care, no prophylaxis; and a tendency toward letting such cases take care of themselves, together with a complete forgetfulness of the golden rule of isolation so far as other people's children are concerned; to say nothing about other members of the same family. The fact that there has been but one death cannot be construed to mean that this epidemic has not been serious; the sequelae tell the story.

"This epidemic has, however, whether intentionally or not, resulted, so far as this generation of children is concerned, in conferring a variable period of immunity, which will serve to protect them until other generations of children come along; then, unless those who have profited by the lesson of this epidemic take heed noting the late example, a repetition at the expense of the usual sufferers—the children themselves—will add another record to the measles history of Nantucket.

"This epidemic also serves to point toward the need of a more efficient school inspection than generally prevails throughout the Commonwealth, *e. g.*, a school inspection that will include school hygiene, personal hygiene and the elementary principles of preventive medicine."

Correspondence.

WAR SURGERY IN FRANCE.

(From Our Special Correspondent.)

LONGUEIL-ANNE, OISE, FRANCE, Aug. 19, 1915.

Mr. Editor: I have been here at the American Hospital now for ten days. The hospital is situated

near Compiègne. At Compiègne, the battle-front changes its direction from nearly north and south, and runs to the southeast toward Soissons. Annel is even nearer the lines than is Compiègne, and the hospital itself is within three or four miles of the angle.

Because of its proximity to the trenches, the hospital receives its wounded within an hour or two of the time of injury. The first dressing is applied by the soldier himself or by his comrades; he is then taken to a *poste de secours*, which is an army dressing station in one of the small villages near the lines. There a superficial dressing is done, and he is brought by ambulance to the hospital. We draw cases from a section some sixteen miles in length, but the comparatively small number of wounded testify to the thoroughness with which the troops are entrenched. Every day the trenches are under fire; especially at night we can hear the jar of bursting German shells, and the sound of the French shells sent whizzing back in answer.

If there were any serious attempt to gain ground in our section, we should be swamped with wounded; as it is, just enough come in to keep the beds comfortably filled. We have only thirty patients at present, but we have some 20 beds vacant and a new barracks now being built will give 25 more.

Most of the wounds are from shrapnel, shells, or bombs. Occasionally a man comes in who has been drilled by a rifle ball.

The most interesting cases which I have seen so far are worth mentioning. One young chap was struck by a shrapnel ball about the size of a marble. The ball entered at the right costo-vertebral angle, fractured the laminae of the 11th and 12th dorsal vertebrae, struck the left kidney, nicked the spleen, perforated the diaphragm, injured the left lung and lodged just beneath the skin of the left axilla. The surgeon under whom I am working had done a laparotomy before I arrived; later, I helped him do a laminectomy. Today we drew off 500 c.c. of thin, bloody, urinous smelling fluid from the left chest. The boy is doing well, although he is paralyzed below the waist. His cord appeared intact, so we hope for a recovery.

The second man was struck by a rough piece of shell the size of an almond in the second interspace just to the right of the sternum. X-ray showed it in the mediastinum, apparently, at the level of the third rib. At operation, the mediastinum was opened from in front, but search as thorough as seemed wise, considering the structure of that region, failed to show it. The man died two days later. Autopsy showed the fragment in the pericardium, resting upon the aorta, surrounded by a small abscess. There was general fibrinous pericarditis, and the right pleura was full of bloody fluid.

It seems that it is very easy to keep these wounds clean if they are thoroughly dressed within the first 24 hours. The sinus formed by the projectile, however, becomes lined with a black, dry slough which takes a long time to clear up. The chief disinfectants which are used in wounds are hydrogen peroxide, tincture of iodine, and a solution advocated by Carrel, who by the way is at Compiègne, composed of sodium hyposulphite with boric acid added. Hypochlorous acid is set free, according to the *London Lancet* of August 14th. This is a powerful antiseptic, but seems to have a deterring influence upon granulation.

The patients themselves are, as a rule, splendid, simple-hearted fellows, and it is a pleasure to look after them. Notwithstanding the very real horror and uselessness of the war, the tragedy of promising young men maimed or killed, one finds much that is admirable—much patriotism, great courage—woven into its complex web.

Yours very truly,

G. G. S.

BELGIAN PHYSICIANS' RELIEF FUND.

REPORT OF THE TREASURER OF THE COMMITTEE OF AMERICAN PHYSICIANS FOR THE AID OF THE BELGIAN PROFESSION FOR THE WEEK ENDING SEPT. 11, 1915.

No contributions for the week ending Sept. 11, 1915.

Previously reported receipts.....\$7814.84
Previously reported disbursements.....7310.04

Balance\$ 504.80

Pittsburg, Pa.

EXAMINATION FOR BOSTON SCHOOL PHYSICIANS.

A competitive examination of applicants for the position of School Physician under the Boston School Committee will be held on September 23, 1915. The salary will probably be \$500 per annum. This examination will be held for the purpose of establishing an eligible list from which names will be certified to fill from thirty-five to forty vacancies existing at present and similar vacancies as they may occur.

Only registered physicians who are citizens of the United States and who have been residents of Massachusetts for the past year and of Boston for the six months last past have a right to apply.

The subjects of the examination will include a sworn statement of training and experience, practice of medicine, and hygiene.

Successful applicants may also be required to undergo a physical examination. Men and women desiring to take this examination may secure application blanks by applying, in person or by letter, at the office of the Civil Service Commission, Room 152, State House, Boston.

By order of the
MASSACHUSETTS CIVIL SERVICE COMMISSION,
WARREN P. DUDLEY, Secretary.

RECENT DEATHS.

DR. CHARLES P. BECKER, who died recently of nephritis in New York, was born in that city in 1844. He received the degree of M.D. in 1861 from the Long Island Medical College and practised his profession until his retirement in 1900. He was for many years an associate editor of the *New York Medical Journal*. He is survived by two sons.

APPOINTMENT.

Dr. H. G. Earle has been appointed professor of physiology at the University of Hong Kong.

NEW YORK AND NEW ENGLAND ASSOCIATION RAILWAY SURGEONS.—The twenty-fifth annual session of the New York and New England Association Railway Surgeons, celebrating the quarter century anniversary of the organization of the association, will be held at Hotel Astor, New York City, October 21, 1915, under the presidency of Dr. W. H. Marcy, of Buffalo, N. Y.

A very interesting and attractive program has been arranged. Railway surgeons, attorneys and officials and all members of the medical profession are cordially invited to attend.

GEORGE CHAFFEE, M.D., Corresponding Secretary,

THE CHILD AND THE COMMUNITY.*

By EDWARD O. OTIS, M.D., BOSTON.

THE CONFLICT BETWEEN NATURE AND CIVILIZATION.

NATURE and Civilization often appear to work at cross purposes. Civilization is all the time trying to accomplish the impossible, of having her cake and at the same time eating it. Nature always makes sure that her cake shall be preserved; and she has the advantage of man in that she can *create* as well as *destroy*. She can eat her cake and be sure of getting another. We, in our ignorance, attribute to Nature a kindly, beneficent attitude in dealing with life, while, if we look a little under the surface, we discover that in the consummation of her plans she is relentless, wasteful, and cruel; but she accomplishes her purpose without the peradventure of failure unless we interfere with her.

One of the inexorable laws of Nature is the maintenance of a type of life which has once come into existence, and to be sure of doing this she sacrifices ruthlessly many other lines of the same type.

"So careful of the type she seems,
So careless of the single life,
That I considering everywhere
Her secret meaning in her deeds
And finding that of fifty seeds
She often brings but one to bear."

But she never fails to bring that one to bear.

* Read before the Advisory Council of the National Association for the Study and Prevention of Tuberculosis at Seattle, June 14, 1915.

Maeterlinck, in his fascinating story of the "Life of the Bees," tells us how, after the nuptial flight has taken place and the one male out of thousands has been selected by the queen bee to be her mate, and the future generations have been provided for, the hundreds of other disappointed males are mercilessly massacred by the working female bees.

"And to serve that single issue
Lest the generations fail,
The female of the species
Is more deadly than the male."

Fabre, in his delightful accounts of insect life, tells of similar tragedies in the life history of other insects.

In the higher animal life, when man does not interfere, Nature shows the same tenacity of purpose in preserving at all hazards the genus though she is prodigal of single lives in doing so.

With man, in primitive life, many children are born; families are large. We see this among the families of immigrants in this country at the present time. In the Colonial days of simple living in New England, marriages were early and there were many children. It is the same among peasant families, for example, and generally among people of primitive habits.

Nature, undisturbed by the artificial conditions of so-called higher civilization, appears to follow, with man, her same general plan for the preservation of the race. She provides lives enough, so that, if many are lost, enough will remain to continue and increase the type,—the race. We see this process of plentiful supply and great loss in the Chinese race, where sixty

per cent. of all babies die before reaching the age of two years, and yet enough are left to maintain and increase the stock.

Civilization, with its so-called culture, appears to contravene this law of Nature to provide enough lives so that, with the loss of many, a sufficient number will survive to continue and increase the stock. The higher we go in Civilization, the fewer the children. Nature says "quantity"; Civilization says "quality",—and loses. We see on every hand the higher types of man decreasing. This is markedly the case at the present time with the old American stock. The old New England families are rapidly dying out. Boston, the ancient centre, one may say, of the pure American race, is now seventy per cent. or more foreign. We cannot, apparently, save the most cultured of our race. The very means we take to produce the intellectually most fit (higher education, careful and prolonged training, refined environment, and all the arts of a higher civilization) appears to defeat its own purpose, by more or less rapidly rendering that higher type incapable of reproducing itself in sufficiently large numbers to maintain and increase its kind. It is a startling and sad fact, but a fact it seems to be.

It is, then, largely to the families of the newer Americans, to the present lower grades of society, that we must look for the future maintenance of our American white population. Our problem is to contravene Nature's law, with regard to man, and see how many of the children in the prolific families of the lower grades of civilization we can save, which Nature, in her prodigality, would allow to be destroyed, permitting only the physically fitted to survive. It is a problem for the community, of the highest economic importance as well as a humanitarian one. As Huxley says: "The influence of that which is ethically best, what we call goodness or virtue, is directed not so much to the survival of the fittest as to the fitting of as many as possible to survive."

EUGENIC MARRIAGE LAWS.

In the first place, the community is beginning to realize that diseased and physically unfit men and women should not be allowed to marry and produce diseased and physically unfit children. In two states, at least, so-called eugenic marriage laws have been enacted. Both for the child's sake and for the sake of the community who have to care for the defectives, such a law seems just and reasonable. It is a significant fact bearing upon this point, that the most important causes of infant mortality in New York City, as stated by Dr. Baker, chief of the Division of Child Hygiene of the Department of Health, in 1913, are the so-called congenital, inherited diseases, the deaths from which diseases occurring during the first month of life, amount to thirty-five per cent. of the total deaths under one year.

CARE OF THE INFANT.

To ensure a healthy child, pre- and post-natal care and training of the prospective mother is essential, and in many communities this is now done in connection with the lying-in hospitals, or, as in Boston, by the Child Hygiene Department of the Board of Health and other private instrumentalities through visiting nurses who instruct the future mothers in personal hygiene, the general care of pregnancy, and in their own and their babies' care after confinement. The Caroline Rest Training School for Mothers, conducted by the New York Association for Improving the Condition of the Poor, is an excellent example of this kind of welfare work.

All communities now recognize the importance of the preservation of infant life, and in all the large cities, at least, there are many agencies at work to accomplish this, some public and others private. Milk stations, with visiting nurses, infant hospitals and dispensaries, welfare stations, departments of child hygiene of city or state boards of health are some of the instrumentalities. In Boston the Milk and Baby Hygiene Association gives care and exercises supervision over a fifth of the baby population of 20,000 up to one year of age. This it does through milk stations or centres where weekly clinics are held with the mothers, and from which nurses go out and visit the homes regularly. In 1914 there were 2007 deaths of babies under one year of age, or 103 per 1000. Of these, sixty per cent. occurred under three months of age.

Although this is the lowest infant mortality of any city in this country except New York, which was ninety-four per 1000 for the same year, yet it is still too wasteful; for, as Dr. Emmons¹ has recently said, "The occupation of being an infant in Boston is more dangerous than being a soldier in the European war." New Zealand leads the world in its low infant mortality, which is fifty-one per 1000, and this remarkable result has been accomplished in large part, says Dr. F. Truby King, through the teaching of mothers pre-natally, post-natally, and later through the milk station.²

First and foremost, the mother should be taught the immense importance, for the present and future well-being of her child, of breast feeding, and that no kind of artificial feeding can compare with it.

CLEAN MILK.

When the baby is weaned, the mother, by ocular demonstration, should be shown how to prepare the milk for that purpose, and afforded opportunity for obtaining clean milk, either raw or pasteurized, and this is now generally possible through the milk stations in the cities. Nothing is of more vital importance in the preservation of the life of babies and young children than the protection of the milk supply, their

¹ BOSTON MED. AND SURG. JOUR., April 29, 1915.

² *Care of Prospective Mothers, Ibid.*

chief source of food, either by certifying it to be clean, from inspected cows, dairies and wherever milk is sold, or else furnishing it in a pasteurized form.

This duty is now recognized in the sanitary code of most well regulated cities. It has been a long fight in the State of Massachusetts to obtain adequate milk inspection laws. Hardly a Legislature passes that the contest is not waged in behalf of clean and safe milk; and it was only a few weeks ago that an efficient milk protection law was finally passed, but which was unfortunately vetoed by the Governor.

The public still needs further education in regard to this surpassing means of conserving infant life. Gastro-intestinal diseases are among the chief causes, as we know, of the high death rate of infants, and they are to a great extent preventable by the use of clean milk. Moreover, the price of safe milk should be within the means of those who can pay but a small sum for it, and it should be furnished free to the very poor, either by the community or through private instrumentality. It must always be insisted upon, however, that during the early months of infant life, no kind of milk, however carefully obtained and modified, can compare with the mother's milk.

After the mother obtains good milk, she should be taught how to take care of it properly at home, that it may remain safe, and for this purpose the distribution of free ice in summer is of great aid. "The infant death rate," says Sir Arthur Newsholme, "measures the . . . standards of morals and sanitation of communities"; and one may add that the provision of clean milk by the community is the one most important measure in reducing infant mortality. The community that does it has thereby established its standard of sanitation and its degree of civilization, for, as someone has well said, "infant mortality is the most sensitive index of the civilization of any community."

FOOD OF THE CHILD.

After the child has graduated from its milk diet, the community has still a duty in seeing that it is provided with proper food. Food inspection laws, so far as they are efficient, and the pure food law protect, to a certain extent, the sources of supply. Instructions in the wholesome preparation of food and food values is afforded through domestic science centres, visitors in the homes of the poor, and the teaching of domestic science in the schools. The mother is to be taught that good and nourishing food need not mean expensive food; but she must possess some elementary knowledge of food values and some experience in properly cooking it.

If the child is insufficiently nourished at home on account of ignorance or poverty, school lunches seem to be the obvious remedy, and the child should be encouraged to bring a few pennies for them; for the parents should be made to

feel that they are primarily responsible for the well-being of their own children.

It is surprising how much good food value can be obtained for a few cents. Here are some sample lunches served in the High Schools of Boston at cost price, providing about one-fourth of the required daily nourishment for boys and girls of fourteen years:—

TABLE I.

Baked beans	5 cents
Graham bread	2 "
Cocoa	3 "
	10 "

Proteids, 23 grs.; fat, 23 grs.; carbohydrates, 80 grs.;
Calories, 605.

For girls of fourteen years:—

TABLE I.

Macaroni and cheese	5 cents
Graham bread and butter	2 "
Milk	3 "
	10 "

Proteids, 22 grs.; fat, 22 grs.; carbohydrates, 65 grs.;
Calories, 570.

TABLE II.

Creamed eggs	5 cents
Graham bread and butter	2 "
Cocoa	2 "
Sponge cake	2 "
	12 "

Proteids, 19 grs.; fat, 21 grs.; carbohydrates, 80 grs.;
Calories, 614.

SCHOOL INSPECTION.

When the child arrives at school age, communities quite generally now provide medical inspection and examination of all school children. In Boston such inspection is now very thoroughly administered by competent physicians acting under the Board of Health, assisted by nurses acting under the School Committee. The physician visits the school every day to detect any case needing urgent medical attention. In addition, he is required to make a yearly physical examination, and oftener if the chief of the division shall so order, of every pupil in the school districts, recording his results.

This examination is very thorough and a long list of defects and diseases is submitted, which the physical examination covers. Examination of the heart, lungs and spine over the clothing is not accepted. Notice of defects de-

teeth is sent to the parents or guardians of defective pupils. School nurses can take children, with the consent of their parents, to the proper dispensaries for treatment or operation, such as removal of adenoids or diseased tonsils.

Thus, from the time the child enters school until it graduates, the community exercises constant supervision over it.

In one of the recent annual reports of the Division of Child Hygiene of the Boston Board of Health, of 118,781 pupils examined, 77,931, or 68%, defects were discovered. The defects originating about the mouth, as defective nasal breathing, hypertrophical tonsils, defective teeth, defective palate and cervical glands were 100,236, or about 84% of all defects found. The dental defects were 51,340, or about 66%.

CARE OF CHILDREN'S TEETH.

Defective teeth furnish excellent foci for bacterial infection, and the tubercle bacillus among other micro-organisms. "Diseased teeth become human culture tubes with ideal culture media for the germs of disease."

What are communities doing to protect the teeth of children, in more than half of whom they are diseased? In Boston there has recently been completed a unique institution, the like of which does not exist anywhere in the world,—an institution to provide for the dental requirements of the children of the city, the gift of two brothers. It is called the "Forsyth Dental Infirmary for Children." It cost \$800,000, and is an imposing marble building, one of the ornamental structures of the city. In addition, an endowment of two million dollars is provided for its maintenance. Not only the care of the teeth is included in its functions, but related oral conditions, such as defective palates, adenoids, etc., and general oral hygiene and prophylaxis. Seven hundred and sixty-eight patients can be treated a day, or three treatments annually of 127,200 children. The staff consists of consulting, visiting and permanent dentists (the latter being paid), and physicians. There is a research laboratory, a museum, and a lecture hall. Complete work is done for each patient, and the child is followed up by the school nurse or some other instrumentality until the entire mouth is clean and healthy, including the nose and throat.

When one considers the opportunities for bacterial infection from diseased teeth and unhealthy oral conditions, and the suffering and disease induced in later life from the neglect of the teeth and mouth in childhood, the value of such an institution can hardly be overestimated. Every community should provide some such opportunity for the care of its children's teeth when the parents are unable to do so.

PLAYGROUNDS.

Another insistent demand of child life which the community is coming to recognize is an op-

portunity for play and recreation, and, through municipal or other instrumentalities, playgrounds with competent supervision are being established in our large cities. A rather novel plan was recently devised in New York City, where, during certain hours of the day, certain side streets were given over to the children, all traffic on such streets being suspended. Well-ordered play is not only the child's natural way of obtaining physical exercise, but it is in the highest degree educative, inculcating unselfishness, self-control and the value of team work,—lessons so valuable in the competitions and associations of after-life. One recalls the saying attributed to Wellington, that he won the battle of Waterloo upon the football field of Eton.

Auxiliary to playgrounds are sand gardens for young children. Many states and municipalities also provide public gymnasiums, baths and bathing beaches, used alike by children and adults.

THE CHILD AND TUBERCULOSIS.

Most authorities now believe that the majority of cases of tuberculosis in adult life become infected in childhood. Thus Hamburger has demonstrated that latent tuberculosis is present in 71% of children from seven to ten years of age. "Our greatest hope for ultimate success in the suppression of tuberculosis," said recently the State Commissioner of Health of Massachusetts, "must lie in the prevention of the development of tuberculosis in the child with a predisposition for, or latent infection of, tuberculosis."

Although open pulmonary tuberculosis is not so frequent in childhood as in adult life, closed tuberculosis is more so, and this form, which is often difficult of diagnosis and is frequently denominated the "pretubercular" stage, may be only suspected by the presence of anemia, malnutrition and debility. For the majority of such children the open-air schools, with intervals for rest and additional nourishment, offer the widest opportunity and are generally sufficient. I am happy to say that such schools are rapidly coming into existence throughout the country. For other children, a *continuous* open-air life in the country is desirable; and for those in whose home a case of tuberculosis exists the safest way is their removal from the dangerous environment. For this purpose so-called preventoria have been established, an excellent example of which is the one at Farmingdale, N. Y., to which children from New York City are sent.

Either by the establishment of such preventoria or by other means the community should protect its children who are exposed to tuberculosis in their homes. It is a general custom now in all tuberculosis dispensaries to submit all the children of a family in which a case of open tuberculosis is present to a careful examination, for Dr. Sachs has shown that in the

examination of such children 28% between the ages of five and ten years, and 25% between ten and fourteen years show evidence of tuberculosis. In 600 patients from the state sanatoria of Massachusetts there were 966 children under fifteen years of age in their immediate families. Of these 362, or 38%, were examined, and the number found to have consumption was 10½%. "The fact stands beyond a doubt," says Prof. Nietner, "that in a very large majority of cases the source of infection is the human subject suffering from 'open' tuberculosis, and that infection is effected through the close intercourse resulting from family life within the walls of the home."

The French "League for the Preservation of Children from Tuberculosis" has for its main object the removal of children from homes where they are exposed to infection, and Prof. Grancher, who established the League, says he was moved to do this from the remark of Pasteur in regard to the diseases of the silk worm, that in order to save a race that is threatened by an infectious disease, the best plan is to save the cocoon.

A very interesting experiment was inaugurated several years ago in New York, in the so-called "Home Hospital." A family in which a case of tuberculosis exists is removed entire to this institution, where they live under the best hygienic conditions. One of the chief objects this experiment endeavors to accomplish is stated to be, "to prevent the spread of tuberculosis from the afflicted to well members of the family, particularly to protect the children from infection."

When a child is found to be actively tuberculous, sanatorium treatment should be provided as in the case of adults. This is already done in many communities. The Boston Municipal Consumptive Hospital has a department for children, and so does one of the state sanatoria of Massachusetts, in both of which school instruction is given when the child's condition permits.

A not infrequent form of tuberculosis in children is that of the glands, bones, joints, spine, and tubercular peritonitis. There is a difference of opinion as to the cause of infection in these cases, but undoubtedly the bovine tubercle bacillus conveyed in milk is the causative factor in some of the cases. This is an added reason why every means should be employed to safeguard the milk supply. Children suffering from these forms of tuberculosis should be provided with sanatorium treatment, either in the country, or better, when possible, at the seaside. Rollier's Sanatorium in Leysin, Switzerland, is a striking illustration of the effects of mountain air and heliotherapy; and the Sea-Breeze Sanatorium at Coney Island, New York, illustrates the value of sea-air and sunshine. Not far from this institution the city of New York has acquired a location with 1000 feet of beach, at a cost of \$1,250,000, where there is in the process of erection a sea-side sanatorium for surgical tuber-

culosis in children, to accommodate 1000 patients, at a cost of \$2,540,000.

CHILD LABOR.

Excessive child labor in mill and factory under an unhygienic environment is a potent means of developing the child's latent tuberculosis or rendering him susceptible to a new infection. Laws have been enacted or proposed upon the subject in almost every state, and in many instances the fight for the adequate protection of the child from such exploitation has been a stubborn one. That the growing child should be subjected to the strain of long hours of the grinding monotony of mill work is manifestly a short-sighted policy, as well from an economic point of view as from a humanitarian one. Not long ago a committee of the Legislature of one of our states agreed that the eleven-hour day was the proper working period for ten or twelve year old children! What opportunity do children thus treated have to develop into vigorous manhood or womanhood? That the child, with its beautiful innocence and trust beyond knowledge, for whom, as someone has said, "the gates of heaven swing inward," should thus be despoiled of its divine heritage of natural child life is a disgrace to our present civilization!

HEALTHY HOMES.

The community again has a duty in the housing of its children. A child should have sunlight, fresh air and cleanliness in its home; for "where the sun enters not, there the doctor comes." Slums with crowded tenements are not inevitable even for the poor, and through boards of health, tenement house inspection and building laws, it is possible, I believe, to provide wholesome dwelling places for the children of the wage-earner even in the large cities. Unsanitary, sunless and ill-ventilated dwellings, where many are crowded into a small space, are favorable conditions for developing the tuberculous child, as abundant evidence has demonstrated.

THE SPIRITUAL DEVELOPMENT OF THE CHILD.

The comprehensiveness of my subject permits me to include almost any and every endeavor which it is the province of an intelligent community to make for the conservation of child life. In conclusion, however, I desire to advert to but one other subject which, it seems to me, should have consideration by the community. When we have provided for the physical well-being of the child and its mental training, there is a third and equally important duty of the community, in my opinion, and that is to offer the child means of spiritual development in the years when its imagination is so active, and it lives so much in the realm of fancy. Ideally, the home and the church are the places and the instrumentalities for doing this; but the home often fails in this duty and, in consequence, fails

to invoke the aid of the church. If we believe that Christianity is the foundation of character, and that character in the individual establishes the character of the community, and that a community of Christian ideals will best protect and conserve its child life, it is, then, of supreme importance that the community should afford opportunity to its children of religious instruction and training. I can see no other way of doing this in a communal way than somehow through the medium of the public schools. A community imbued with an altruistic, a Christian, spirit, can be depended upon to care for its children, and needs not to be coerced by law to do certain things needful for their welfare, or deterred by the menace of punishment to refrain from doing things harmful to them. The spirit of the community will dictate the actions of the community, and if a community believes the words of the Master relative to the child, that "of such is the kingdom of heaven," it will guard and protect the child so that it may grow towards physical and moral perfection, an exemplar of the Christ-child.

CONCLUSION.

The child, with its innocence, its faith, its mysticism, nay, its very ignorance, should appeal, if anything can, to the very best instincts of the community, as well as to its selfish interests, for the child of today makes the community of tomorrow. Whatever the physical, mental and moral education of the child is *now* will be reflected in the character and standards of his day when he transmutes his present training into action. "It would be a dreadful calamity," said ex-President Roosevelt, "to continue to waste and destroy the resources of the nation, as until a few years ago we were wasting and destroying them, as we still, in certain respects, continue to waste and destroy them. But it would be even a worse calamity, because irremediable, if we wasted and destroyed the manhood and womanhood of the nation. And the only way permanently to conserve the manhood and womanhood is to conserve the childhood."

Original Articles.

TRANSVESICAL PROSTATECTOMY: A DISCUSSION OF SOME UNSETTLED POINTS IN THE PREPARATION FOR AND TECHNIC OF THE OPERATION.*

By PAUL M. PILCHER, M.D., BROOKLYN, N. Y.

THE occasional surgeon, or the surgeon unacquainted with the science of urology other than as it crosses his path in the operating room, does not need to discuss the disputed questions

concerning obstruction at the neck of the bladder due to prostatic hypertrophy or distortion. To this sort of man a complete examination of the patient is not necessary. All that he needs to know is that there is an obstruction at the neck of the bladder, that it is probably due to an enlarged prostate, and that it can be removed surgically.

If he is lucky his patient will survive his operation, with the chances of more or less permanent disability. This is sufficient for some men. To others of us who have passed through the developmental stage of prostatic surgery, who can look back upon an uncontrolled hemorrhage, the unexplained death of some patients whose good general appearance lured us into a state of false security, we feel that we need a great deal more information in order that we may know beforehand what to expect in a given case and to choose, if may be, the safest course to pursue under the circumstances.

To my mind, a thorough examination is most essential. I believe that we should determine, if possible, before operation whether the obstructing prostate is due to cancer, or to simple adenoma; whether there is a stone present in the bladder; whether the symptoms are due to the presence of this stone or not; whether there is a new growth present in the bladder. I have seen all of these conditions in cases in which I had expected to find only a simple hypertrophy of the prostate, the mistake being due, I believe, to my own carelessness in not making a thorough and exhaustive, but not exhausting, examination of the patient.

Aside from the ordinary vesical examination at our clinic, we employ first the x-ray to determine the presence or absence of stone in the bladder. Sometimes we are able to determine the outline of the prostate.

Next, we pass a simple examining cystoscope, such as that devised by Wappler especially for this work, constructed with a beak curved like an ordinary sound. We find we are sometimes able to introduce this cystoscope into the bladder when catheters fail. A thorough cystoscopic exploration is made, if possible.

Both the cystoscope and the x-ray are of advantage in that a stone may be hidden in a diverticulum and not be seen by the cystoscope. In these cases the cystoscope also determines the presence or absence of a new growth.

CANCER OR ADENOMA.

Rectal Examination is important in helping us to determine between cancer and adenoma. We suspect cancer in all patients under 60 years of age, who have had any considerable degree of obstruction. We have had cases of adenoma in men between the ages of 55 and 60, but very few in number. We suspect cancer when the symptoms are rapid in their onset. By that I mean have been complained of only for a year in older patients. It has been our experience

* Read at the winter meeting of the New England Branch of the American Urological Association in Boston, on March 20, 1915.

that the patients with the longest histories of frequency of urination, etc., are the least apt to have cancer of the prostate.

Primary tuberculosis of the prostate has been met with in one patient of 55 years of age. It simulated cancer in its general characteristics.

There are other differential points which it is not necessary to go into at present, but from the standpoint of treatment as adopted at our clinic, it is quite important for us to know beforehand, if possible, whether the case is one of malignancy or simply adenoma.

I believe it is universally accepted that all cases of prostatic obstruction should receive more or less preliminary care. The question of what form this treatment should take has not as yet become standardized, but in the majority of cases it has resolved itself into a question of drainage of the bladder; either using a catheter to empty the bladder at regular intervals for a given period of time, the use of an indwelling catheter, or the establishment of suprapubic drainage by means of a cystostomy.

CHOICE OF METHOD FOR RENAL DECOMPRESSION.

As a temporary expedient intermittent catheterism is simple and efficient. Its dangers include the possibility of septic infection, which in certain individuals is a minimum risk, but in the majority of cases the continued use of a catheter

is sure to result in a train of septic consequences of the most serious character. Again, there is the danger of profound constitutional reaction, which has been occasionally observed following the simple use of a catheter, so profound in some cases as to terminate in death in a few hours. Occasionally in some cases each attempt at catheterism is followed by a more or less septic condition. These observations refer more especially to the advanced cases of prostatic obstruction where cystitis is present and the obstruction has existed for a sufficient time to cause renal insufficiency and more or less invalidism. Intermittent catheterism used early for the beginning stages of chronic prostatism is almost devoid of danger.

The *catheter a demeure*, where it can be tolerated, is free from criticism, other than the unnecessary amount of irritation of the urethral mucosa which results from its presence in the urethra. It must always be remembered that danger accompanies any method which might bring about a sudden emptying of the bladder that has been distended for any length of time.

Suprapubic cystostomy is attended by the dangers common to all minor surgical operations; it can be done entirely under local anesthesia, with practically no surgical shock attending it. It completes the first step of the operation of transvesical prostatectomy and affords

FIG. 1.—Showing the surgical problem. Special attention should be directed to "A", the fold of peritoneum in its relation to the symphysis when the bladder is contracted. "B" the raising up of the peritoneal fold when the bladder is dilated. The relation of "A" and "B" to the symphysis is quite variable and in some is fixed almost at the symphysis.

temporary relief to urinary prostatic obstruction, while the best general and local conditions are being secured for the later radical removal of the obstruction itself. It is free from any reflex effects which attend the introduction or residence of a catheter in the urethra. It has still further the advantage not only of easy and adequate urinary drainage, but also of placing at rest the urethral tract and of being the most powerful agent in overcoming any reflex influence which the irritation of that tract may previously have been producing. Furthermore, if a foreign body is present in the bladder it may be removed at this time, without the added disadvantage of surgical shock. The tissues through which the bladder is explored, are exposed to infection, without the depressing systemic effects which accompany a major operation.

In advanced cases, we believe that repeated catheterism is wrong. We do not object to the indwelling catheter under certain conditions, and at times feel that it is distinctly indicated, especially in those cases where there is an enormous distention of the bladder with edema of the legs, and as a routine when there is an enormous over-production of urine. In the presence of intravesical hemorrhage, advanced infection, or large calculi, we feel that suprapubic cystostomy is the method of choice as a preliminary to transvesical prostatectomy.

At our clinic we perform a suprapubic cystostomy as a preliminary operation in every case of prostatic hypertrophy due to simple adenoma, even though we have used an indwelling catheter previous to this.

The chief objection to the two-stage operation

has been the discomfort due to leakage of urine over the abdomen of the patient. This has been overcome at our clinic by adopting the following technic:—

Operative Technic of First Operation. Preferably with the bladder filled with fluid, a suprapubic cystostomy is done under local anesthesia, using one-half to one-quarter per cent. novocain solution to infiltrate the tissues. The points of the technic which we emphasize are: 1. Exposure of anterior surface of bladder as high up as possible. 2. Making opening in bladder at least three inches from urethral opening (Fig. 2). 3. Drainage of bladder by Pezzer catheter or Pileher modification. 4. Purse string suture around opening in bladder to secure water-tight joint (Fig. 3), employing same principles as in drainage of gall bladder. 5. Immediate resuture of suprapubic wound, obliterating prevesical space, reconstruction of the facial planes, etc., and closing the wound without drainage except where button drainage tube emerges. (Figs. 4 and 5.)

Results. 1. Primary union of wound in practically every case.

2. Absolutely dry wound without any leakage of urine.

3. Complete control of urine for tests.

4. Patient out of bed in 24 hours.

5. Half of the operation complete without anesthesia or surgical shock.

Question of when to operate. Our rule is that as soon as the bladder can be safely emptied the suprapubic cystostomy should be done. In all cases of emergency, where there is active hemor-

FIG. 2.—Showing the position of incision into the bladder preferably at a point three inches from the urethral opening. The peritoneal fold has been reflected high up.

FIG. 3.—The Pezzer or Pilcher catheter secured in anterior wall of bladder held in place by purse-string suture, secured similarly to tube in drainage of gall-bladder.

rhage into the bladder, suprapubic cystostomy should be done.

How long shall we wait before removing the prostate? In some cases we can determine within two or three days that any time will be suitable for removal of the prostate. In other cases

we feel equally sure that the prostate could never be safely removed. In general, after a suprapubic cystostomy has been performed and the patient is out of bed, if his general bodily functions are working well, his mind is bright, his eyes are clear, his urine is nearly normal, of good specific gravity, containing only a trace of albumin; when the phthalein test shows an efficiency of from 30 to 50%; when the patient is sleeping well and eating well, we feel perfectly safe in removing the prostate. We prefer, as a rule, to wait eight or ten days after the first operation in order that we may have a more perfectly healed suprapubic wound through which to work, for under these circumstances we have a shorter convalescence and the urinary fistula closes more quickly.

Another thing which I believe is quite important is that one should never try the second operation unless he can have a patient under observation more or less continuously for the 48 hours following the operation. In other words, we should not perform the operation out of town at so great a distance that we could not reach the patient within an hour.

In the more advanced cases where there is a severe depression, in what we have termed the second stage, the problem is not quite so easy. We may have to wait weeks or months before we feel that the patient is in proper condition for his second operation.

In studying the question of renal functions,

FIG. 4.—A bladder drained by Pezzer or Pilcher catheter showing wound entirely closed about catheter and the relation of catheter button to prostate. This method drains the bladder completely without any leakage.

we have found that there are *two distinct factors* which are helpful in determining the probabilities of recovery. People seem to forget the fact that the kidney is not the only organ upon which life depends, and, if we find that the renal function is sufficient, the patient may die from vascular disturbance, cardiac failure, apoplexy, surgical shock or any one of the different disturbances.

In trying to determine, however, the functional sufficiency or impairment of the kidney, we recognize three distinct factors which may be roughly designated pre-renal, renal and post-renal periods. These factors have been discussed in other papers. The phthalein test gives us the index of renal sufficiency at a given time, and a series of phthalein tests taken under varying conditions,—pre-operative, post-operative and during the convalescent stage, gives us an index of the stability of renal sufficiency, so that in each of our cases we must determine, if possible, both of these indices, that of efficiency and that of the stability of the renal sufficiency. We have learned that, when the renal efficiency is very low, that is, below 5 or 7% in two hours, it is very unsafe to attempt a prostatectomy.

The speaker showed a series of lantern slides demonstrating the various features of the two-stage transvesical operation, showing first the technic of the first operation, charts of individual cases used in determining the time for the

second operation, the technic of the transvesical prostatectomy pointing out the methods employed at the Pilcher clinic for enucleating the prostate, emphasizing the importance of removing all debris from the bladder and searching for small prostatic stones which might have been left in the bladder, then describing the suprapubic drainage following the second operation in which a large calibre drainage tube is used for 24 hours. This tube is removed after 24 hours and a button catheter inserted in its place. This button catheter controls the output of urine from the bladder within two or three hours and again the patient remains dry.

In discussing the control of hemorrhage the speaker recommended the use of the Hagner bag and presented a modification of his own, which consists of a bag through which a catheter is led out, which drains the bladder from below.

The most important step which has been worked out after the second operation consists in removing the drainage tube after 24 hours and inserting the button catheter in the bladder, and draining through the button catheter for three days, and then putting a cork in the button catheter and having the patient empty his bladder voluntarily every hour for a period of three or four days, then removing the button catheter, and it will be found that the patient continues the urination. This has been a very great step in advance at the clinic.

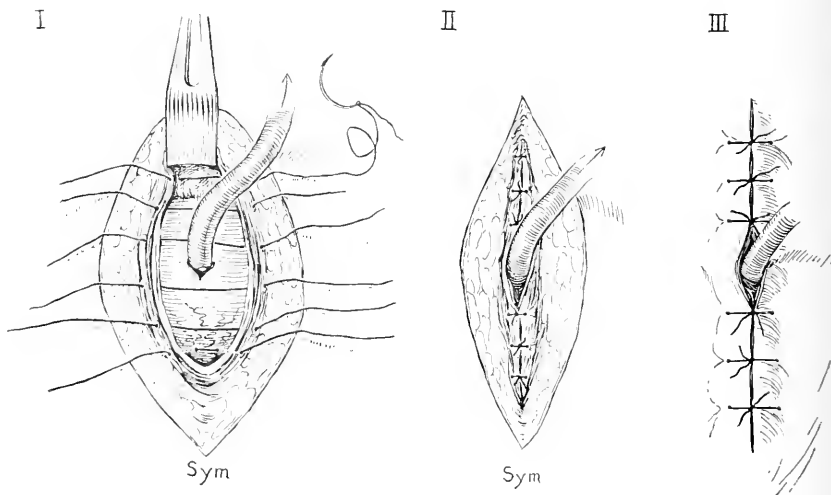

FIG. 5.—Various stages in closing of wound after suprapubic cystotomy.
 I. Placing the first suture, the lowest suture closing off the prevesical space and including wall of bladder, the second and third sutures drawing together the rectus fascia and the upper three sutures drawing together the fascia below the peritoneal fold.
 II. Further tying of sutures and closing the wound tightly around catheter.
 III. Suturing the skin with silk. Closing wound around catheter without drainage. These wounds heal almost invariably without infection.

A STUDY OF THE EFFECT OF ROWING ON THE HEART.

BY ROGER I. LEE, M.D., BOSTON;

WALTER J. DODD, M.D., BOSTON;

AND

EDWARD L. YOUNG, JR., M.D., BOSTON.

AN abundant and somewhat contradictory literature has grown up concerning the effect of exercise on the heart. Shumacher and Middleton¹ give an extensive bibliography and a brief resumé of some of the more important work. One of the most important aspects of this disputed point is the effect of our present rather elaborate system of competitive college athletics on the heart. Shumacher and Middleton, in a study of athletes at the University of Wisconsin, incline to the view that athletic training at first leads to physiological hypertrophy, but when prolonged and marked by severe athletic contests it usually leads to hypertrophy, plus dilatation of a variable degree, frequently marked by valvular insufficiency. While they grant that the hypertrophied heart, even when dilated and giving distinct evidence of valvular insufficiency, may prove more fitted to carry a man through a severe athletic contest than a normal heart, they believe that the so-called "athletic heart" is a distinct disadvantage to normal human activities. On the other hand, James MacKenzie² of England, with his wide experience in cardiac disease, seriously doubts the existence of any such pathologic condition as the so-called "athletic heart." MacKenzie maintains that "the evidence on which the heart's impairment was based was those manifestations of murmurs or irregularity which my experience had shown to be perfectly consistent with a healthy heart." Cabot³ analyzed 600 successive and unselected cases of patients with the signs of a failing heart with the purpose of determining the etiologic factor. In no case was he able to attribute the cardiac impairment to athletics or immoderate exercise.

Perhaps the most constant assertion of the believers in "athletic hearts" is that these hearts are enlarged. The evidence of enlargement has been based usually on percussion outlines, but more recently on Roentgenologic data, and sometimes on both, as in the work of Shumacher and Middleton. There are serious objections to evidence based solely on percussion findings. In the first place the accuracy of percussion can be questioned, as a comparison of the normal percussion outlines as given by various standard text-books shows. In the second place, a very large element of personal equation is introduced. The Roentgenologic examination, even as perfected, has also certain drawbacks. Posture, breathing, the distance of the x-ray tube,—all distort the cardiac picture. For example the size and shape of the heart is quite different in forced inspiration and in forced expiration. Again, the x-ray tube will project a

shadow of much larger size when near the heart than when distant. However, it has been determined that with the x-ray tube seven feet distant no appreciable error is intruded, since the rays at that distance are essentially parallel. It has further been determined that during quiet breathing, that is, in the absence of forced inspiration and forced expiration, the contour of the heart is constant. It seems, therefore, that with this method, certain reliable data ought to be obtained. That is the method which we have used in this study. We have omitted purposely in this particular study the effect of a single athletic contest on the size of the heart. We have also omitted the effect of a single period of training. The important consideration as we see it is—does prolonged participation in athletics cause a permanent enlargement of the heart? It must be granted that participation in violent athletics may cause other impairments than increase in size. Unfortunately, at the present time there seem to be no adequate discriminating criteria of those impairments other than the well known methods of auscultation and blood pressure determination. Furthermore, our evidence is based on individuals who have participated in one form of athletics, namely, rowing, since by common consent rowing has been supposed to have been the most conspicuous cause of athletic hearts. Our individuals have been trained under a uniform system and under careful medical supervision. It is possible that the results which hold in Harvard University are not applicable to other conditions, in other universities and elsewhere.

For the purposes of study three groups were selected. Group I consisted of sixteen freshmen, who were chosen for two reasons: (1) they were essentially of the same build as individuals of the other group who had already participated in hard rowing contests; (2) it is hoped by repeating the observations on Group I throughout their college course, especially if some of them participate in strenuous athletics during that time and some do not, to secure more definite data. All the members of this freshman group were individuals of the vigorous type of young manhood. As is common in such types, all had been rather active in physical exercise, a few had rowed previously.

Group II consisted of 16 candidates for the university crew, 3 were seniors, 8 were juniors, and 5 were sophomores. The five sophomores rowed in the class crew race in June, 1914. Four of the 16 had rowed in a varsity four mile race. Six had been on the Harvard second crew that went through the same preliminary period of training for the four-mile race, but raced at Henley, England, in July, 1914. Therefore they were all athletes with a definite period of athletic activity behind them. The third group consisted of ten graduates; this group averaged over ten years of rowing. All had rowed in a four-mile intercollegiate race in their college years and all had been active in competi-

tive rowing since graduation. Seven were members and one a substitute in the Union Boat Club crew that raced at Henley in July, 1914. The other two were men who had participated in many rowing races since graduation.

On physical examination there were no irregularities in heart action in any of the groups. On a single examination there were no blood pressure observations that could be interpreted as abnormal. The urines of all were free from albumen and sugar. None of the three groups presented any evidence of cardiac enlargement by the usual methods of percussion and auscultation. One of Group I, that is, the freshmen, presented a murmur which was interpreted as functional. One of Group II presented a similar systolic murmur. Two of Group III presented very slight functional murmurs. Some of each group were supposed to have athletic hearts. None of these had murmurs.

The Roentgenological examinations were made during February and March, 1915, before the active rowing season. The examination was made under identical conditions by the method previously stated. The pictures were all taken standing and the x-ray tube was carefully placed on a level with the mid-portion of the thorax at the seven-foot distance. In addition fluoroscopic examinations were made in each case, but showed no abnormality. By the use of calipers the antero-posterior and lateral diameters of the chest were determined in the line of the nipples.

The appended tables show the details. Groedel's table, giving the average size of the heart in male adults of a similar height, is also appended. Groedel used the orthodiagraph method, which in our hands has not given so satisfactory results in regard to accuracy as the seven-foot plate method. Furthermore, Groedel's method gives a slightly smaller reading than is obtained by our method. Groedel utilizes in his table all types of individuals of a given height and strikes the average. It has seemed to us that it is reasonable to suppose that muscular types should be compared with the same types with and without athletic competition. We hope to establish later a standard for different types. With the present wide prevalence of various athletic activities it has been impossible to obtain any considerable group of that type, since practically all of them at some time had participated in athletics to a certain extent that would render their use as a standard open to criticism on critical analysis. One individual is included who had never participated in any athletic contest, even in his school days and who had for many years taken very little exercise. He is included as giving an interesting, but not important comparison.

From the tables it will be seen that the freshmen show an average width of the heart of essentially 13 cm., varying from 11.5 cm. to 14.2 cm. The varsity candidates show an average width of 13.85 cm., varying from 12.7 cm. in a junior to 15.1 cm. in a sophomore. The grad-

uates give an average width of the heart of 14.04 cm., varying from 11.5 cm. to 15.5 cm. The non-athlete shows a width of 14 cm. Groedel's average is 13.2 cm. It will be seen that the hearts of the younger freshmen are somewhat smaller in width than those of the varsity candidates or the graduates. The difference between the varsity candidates and the graduates is surprisingly small, 19 cm. or 1/13 of an inch.

In a similar way a comparison of the length of the heart shows that Groups II and III are very close and the freshmen show hearts that average somewhat shorter, although even here the freshman length is greater than the normal average, as obtained by Groedel's method. The non-athlete had a short heart, well below Groedel's average and considerably below the average of all the groups.

The width of the aorta was also measured and showed similar findings, namely, Groups II and III were very close, and the freshmen group gave a reading slightly smaller.

It is apparent then that there is no real difference between Groups II and III, although Group III averages 8 years older and averages several years more of strenuous athletic participation. The increase in age and increased athletic activity has had no effect upon the size of the heart. The freshman hearts are slightly but definitely smaller than the other two groups. The difference can hardly be attributed to the difference in weight or height, because those differences between the two groups are too slight. The freshmen are, of course, the youngest group, but there is much less difference between the average age of the freshmen and the average age of the varsity candidates than between the varsity candidates and the graduates. An important consideration, however, is—have the freshmen attained their maximum development both in regard to general skeletal and muscular development and also in regard to their heart? Anyone familiar with undergraduates appreciates the fact that the average freshman has not reached his maximum development. That would not necessarily hold true of these individual freshmen. Casual inspection, however, discloses that while the freshmen group are as tall and weigh as much as the varsity and graduate students, the freshmen are very apparently not so well developed or muscled. The measurements of the diameters of the chest taken during quiet breathing gives rather interesting information. The freshmen averages were 29.25 cm. and 19.34 cm., the varsity averages were 29.87 cm., and 20 cm., the graduates were 31.6 cm. and 21.6 cm. Here for the first time we see a gradual increase running through the three groups corresponding to the age differences. Curiously enough, however, the increase in age and increase in chest diameter in the graduate group is not associated with an increase in the size of the heart. In attempting to find some relation, particularly in regard to development, it was found that the total of the two diameters of the chest in centimeters, plus the

average age in years of Groups I and II corresponded almost exactly to the totals of the average width and height of the heart. Further work must be done to establish the consistency of this relation, but the relation in these two groups is of interest.

SUMMARY AND CONCLUSIONS.

Tables are appended which show that there is very little difference in the size of the heart of men who have been rowing for two to four years and men who have been rowing over ten years. The hearts of these two groups are very slightly larger than the hearts of a younger group who have not as yet participated in serious competitive rowing. These differences seem to be explained by the differences in age and development. The only conclusion that can be drawn at this time from this particular study is that prolonged participation in rowing under the system now in vogue at Harvard University and the Union Boat Club of Boston does not materially increase the size of the heart when the heart is sound at the beginning.

EXPERIMENTAL AND CLINICAL OBSERVATIONS ON THE BLOOD-PRESSURE IN SPINAL ANESTHESIA.*

By GEORGE G. SMITH, M.D., BOSTON.

THE use of ether in urology has been attended by certain dangers, the chief of which resides in its effect upon the kidneys. It seemed, therefore, when spinal anesthesia was made practicable, that this method for urological cases would prove to be ideal. In many instances, such has been the case. In others, we have been distressed by the severe and alarming fall of blood-pressure which accompanied and was apparently due to this method of anesthesia.

In a number of our spinal anesthetics in which the blood pressure was followed, there was a marked fall, which in some cases amounted to 100 mm. of Hg. In several cases the blood pressure fell even below 45 mm. Hg., which was the lowest level recorded by the clinical apparatus. These extremely low pressures occurred only in a small proportion of spinal anesthetics; in most instances the blood pressure fell to 75 or 80 mm. Hg. Always with the more pronounced drops, and at times with the drops of moderate degree, the patient exhibited the signs of shock—namely, pallor, sweating, nausea, air hunger and a pronounced sense of uneasiness. The pulse al-

ways remained between 60 and 90, and did not increase in rate as the blood-pressure fell. The above mentioned signs appeared in from 10 to 20 minutes after the introduction of the drug, and passed off as the blood-pressure began to rise, which it usually did 10 to 15 minutes later. Several cases which had been through this rapid change of blood pressure had cardiac decompensation within 24 to 48 hours after operation, and although the influence of the operation (usually suprapubic prostatectomy) could not be disregarded, it seemed to us that the spinal anesthesia might well have been an important factor in disturbing a heart which was perhaps not in the best condition to go through such an ordeal. It is fair to say that none of the cases in which a minor operation or cystoscopy alone was done had cardiac decompensation afterwards. It may be that as most of the cases of this class were young men, their cardiovascular systems were better able to stand the fluctuations in blood pressure, whereas the older men, who had prostatectomies, were often in advanced arteriosclerosis.

However that may be, it is a fact that in a considerable percentage of cases the blood-pressure fell to a disturbing degree. Physiologists have found that in animals in which a blood pressure of less than 35 mm. Hg. is induced for more than 15 minutes, a number of nerve cells are actually killed from anemia and the consequent lack of nutrition. It is not unlikely that the very low pressures sometimes seen during spinal anesthesia contribute to post-operative shock through depriving the higher centers of their proper blood supply.

The occurrence of this fall in blood pressure in some cases seemed to us a danger grave enough to contraindicate spinal anesthesia in those very cases in which its use, from other points of view, was most desirable. With a view to finding out the cause of the low pressure, and if possible a means of preventing it, I took the question to Dr. W. T. Porter, and in the laboratory of comparative physiology of the Harvard Medical School we attempted to solve it through experimental methods.

The cat was the animal selected. Fifty were used, and as in many of them more than one experiment was done, we gathered records of 74 different injections.

The cats were lightly anesthetized and then stretched on the cat board. The carotid artery was exposed, connected with a membrane manometer, and a cannula was put in the trachea so that artificial respiration could be established. We found that the changes in blood pressure and the tests of anesthesia were so much influenced by muscular reactions that we could not tell for sure just what was happening, and if the cat became too deeply etherized the reflexes disappeared. Therefore, we abandoned the use of ether throughout the experiments and used curare alone. The animal was turned over on its belly and, as I found that it was impossible to

get the needle into the dura with certainty without doing a laminectomy, in every case laminectomy was done. We are well aware that there are certain forces within the spinal sac which keep up the movement of the spinal fluid. It is known, for instance, that respiration tends to cause movements of the spinal fluid; this effect must have been more or less offset by these windows through the spine. Also in considering the effect of gravity, one must allow for the influence of atmospheric pressure when the tube is open at the end. We tried to make allowances for these sources of error, and we feel that the information obtained is substantially accurate. The needle was inserted through the dura and the fluid injected into the cerebro-spinal fluid at the lower lumbar region, where the cord becomes very small. In that region the needle can be inserted perpendicularly into the long axis of the cord. Higher up the needle has to be inserted more or less parallel with the axis of the cord, and the direction of the injection is thereby changed. We have endeavored to consider all these factors in noting the principles underlying the distribution of the drug.

Tropacocaine and novocaine, with and without adrenalin, were the drugs used. Adrenalin alone injected into the spinal canal was found to have no effect upon the blood-pressure.

The literature from 1900 to March, 1915, contained no conclusive work on the blood-pressure during spinal anesthesia. A number of writers mentioned the fall in blood-pressure, but attributed it to the effect of the drug upon the bulbar centers. In our experience with cats under ether alone, if the injection was made into the spinal sac below the phrenic nerves (5th cervical) and ascended to the medullary centers, respiration was always paralyzed. In the 125 cases in which spinal anesthesia was used on the genito-urinary service at the Massachusetts General Hospital, no case showed respiratory paralysis. The fall of blood pressure, therefore, cannot be attributed to the influence of the drug upon the bulbar centers.

It has been shown that the blood-pressure is dependent largely upon the condition of the blood vessels of the splanchnic area. The mechanism by which the pressure in this area is regulated consists upon its efferent side of three links: (1) the bulbar centers, (2) the efferent vasomotor tracts which run in the antero-lateral columns of the cord, (3) the vasomotor fibres which pass out with the anterior roots of the cord from the 5th dorsal to the 3d lumbar segments. (Howell: American Text-book of Physiology, vol. i, p. 206.)

In our experiments it appeared that all of these links of the vasomotor mechanism were susceptible to paralysis by novocaine. When, however, the drug is injected in the lumbar region, as in spinal anesthesia, its effect as it diffuses throughout the spinal fluid is felt first and chiefly by the vasomotor fibres of the anterior roots.

Several typical experiments are illustrated by the accompanying figures, the legends of which contain the essential facts. (Figs. 1, 2, 3, 4.)

FIG. 1.

Experiment 45, Feb. 26, 1915. Cord exposed at L. VII and D. XI. Curarized cat. Scale 50, 70, etc.
1 c.c. of 1% Novocaine and Ad. "C" at L. VII at 12.22 P.M. causes fall of blood-pressure from 100 mm. to 55 mm. in three minutes. Diminution of brachial reflex and paralysis of dorsal columns at D. XI.

6. Lumbar VII.....	10.25

As a result of our work, the following conclusions may be drawn:—

1. The blood-pressure can be lowered as much by spinal anesthesia as by section of the cord in the cervical region.

2. The greatest fall was caused by injection of the drug in the thoracic region, where the vasomotor fibres which supply the splanchnic area leave the cord.

3. This part of the vasomotor mechanism is the first affected by the drug when the injection is made in the lumbar region.

4. The extent of diffusion of the drug within the dural sac appears to be influenced more by the bulk of the solution injected than by any other one factor.

5. A given amount of drug in a concentrated solution diffuses less and consequently lowers blood pressure less than does the same amount of drug in a more dilute solution.

6. The greatest effects upon blood pressure were noted when adrenalin was combined with novocaine.

7. Entire fixation of the drug does not take place within 20 minutes after the time of injection.

8. When a solution of greater specific gravity than spinal fluid is used, the extent of diffusion may be increased by gravity.

9. Attempts to raise the blood pressure by the intravenous injection of pituitrin or adrenalin gave only a very transient rise.

Clinical Department.

PITUITARY EXTRACT AS HEMOSTATIC IN HEMORRHAGES OF THE LUNGS.

By M. J. KONIKOW, M.D., BOSTON.

In the ever-increasing literature on the pituitary extract and its action, we have not come across a single case where this extract has been used as a hemostatic in severe hemorrhages of the lungs. True, Bab¹ reports its action as gynecological stypticum, while Etienne,² Hamburger,³ Lewis,⁴ Klotz⁵ and many others dwell upon its action on the blood pressure. The latter recommends it especially in uterine hemor-

rhages due to postpartum atony of the uterus. He also thinks it may be of value in other hemorrhages dependent upon a low vasomotor tone, although he has no personal experience with its use in such conditions. Wiggers⁶ and Pal⁷ observe its constrictive action on peripheral blood vessels, thus producing a marked rise of arterial blood pressure. But a definite mention, to our knowledge, of the use of this extract in hemorrhage of the lungs is lacking. This in our opinion should serve as a sufficient justification in reporting the following case:

S. F., druggist, 32, married, two children.

Family History. Negative.

Previous History. When a child of six, had a long-standing cold abscess on the left side of the chest, which eventually emptied itself in two places, and left two considerable scars with some retraction of the left chest wall. Had his first hemorrhage from the lungs 13 years ago, from which he recovered in a few weeks. Three years ago had another hemorrhage with same good results. During these three years patient was working hard, stayed late hours in his store, had little sleep and irregular meals, with very few chances for outdoor exercises.

On June 2, 1915, he was overtaken with a severe hemorrhage and had to be carried home in a taxicab.

Examination. On my arrival I found him in bed, still coughing up and spitting considerable blood. Pulse was rapid, easily compressible, 104 per minute. Any further examination, in view of the conditions, was postponed for a future time. Ice was ordered internally and externally. In the absence of morphia, it occurred to me that pituitary extract might be a good substitute. One c.c. of "pituitary liquid" (prepared in one c.c. ampoules, each supposed to contain 0.2 grams of the fresh posterior lobe of the pituitary body of the ox) was injected hypodermically.

The result was magical. Within ten minutes the pulse dropped down to 76, it became less compressible, the heart slowed down in its action, the patient was coughing up less and less blood, and at the end of 30 minutes he was expectorating only slightly colored sputum.

Consequent History. For four days patient was spitting blood only in the mornings, in very slight quantities, about the size of a pea each time. In about ten days patient felt so good, that he ventured to go down and out two nights.

Another hemorrhage occurred. Similar condition of the pulse and heart found. Again "pituitary liquid" was used with the same excellent results. A week after a third hemorrhage occurred. In my absence another physician was called in. Codeine in 1/6 of a grain doses was given per mouth. I saw the patient sixteen hours after this attack. He had the worst attack he ever had, and the hemorrhage at the time of my examination was still continuing. Every cough would produce a mouthful of blood. His pulse was very weak and rapid, heart beats accelerated, at times irregular. A hypodermic injection of the same "pituitary liquid" was administered, and, in view of a threatened collapse, followed by 1/30 of a grain of strychnin. Patient responded quickly in the same manner. He made a steady recovery and is at the time of this writing enjoying a country vacation.

SUMMARY.

This case suggests that in pituitary extract we have a powerful hemostatic in pulmonary hemorrhages. The *modus operandi* here is probably based upon the same principle as its action on the uterus as an oxytocic. In both cases the results are due to the constrictive action on the peripheral blood vessels, in the first instance checking by it the hemorrhage, in the second instance producing by it a temporary anaemia of the uterine muscles, which in its turn causes their contractions.

Reports of Societies

NEW ENGLAND BRANCH OF THE AMERICAN UROLOGICAL ASSOCIATION.

WINTER MEETING HELD MARCH 30, 1915, AT THE HARVARD CLUB, BOSTON, MASS.

President, DR. A. L. CHUTE, Boston.

Secretary, DR. R. F. O'NEIL, Boston.

PRESENTATION OF SPECIMENS, INSTRUMENTS, AND REPORTS OF CASES.

A CASE OF TOTAL CYSTECTOMY FOR MALIGNANT DISEASE OF THE BLADDER.

DR. A. H. CROSBIE, Boston: I have here a specimen of a bladder that I believe will be of interest to you. It is from a man fifty-seven years of age, whose symptoms began four months before he presented himself, and upon whom I did a total cystectomy because of a malignant growth involving the region of the right ureter. This man showed nothing characteristic in the way of symptoms, just a turbid urine with frequent and painful urination.

Cystoscopic examination showed that his symptoms were due to a tumor about the size of a small hen's egg, involving the right ureteral region and orifice. Not only did this mass which had the appearance of a malignant mass, involve the region of the right ureter, but it extended so near to the bladder outlet as to make any partial cystectomy, even with transplantation of the ureter, seem out of the question. Therefore, total cystectomy was decided upon.

At the first operation, which was done three weeks before the cystectomy, I did a double lumbar ureterostomy, allowing three quarters of an inch of

the ureter to project beyond the surface of the loin. The right ureter was found very considerably dilated at this time, and the urine slightly turbid. The patient suffered from two attacks of pyelonephritis of moderate severity during the interval of three weeks between the ureterostomy and the cystectomy. This interval between the operations was determined upon, because in another case of double ureterostomy on the urinary service at St. Elizabeth's Hospital it was found that the patient suffered from repeated attacks of acute pyelonephritis following operation, in fact, died of this cause. I therefore wished to wait until this patient developed a certain immunity in this regard. The ureters during this time swelled up very considerably and a considerable part of one of them sloughed away, due, I believe, to cutting off the blood supply with the stitch with which I anchored this ureter to the skin of the loin.

On March ninth the urethra was exposed through a transverse perineal incision, cut across and freed up to the general region of the prostate. The incision was packed lightly, the patient put in the dorsal position with his pelvis slightly raised and a median abdominal incision made. The perivesical space was opened without opening the peritoneum and then the peritoneum was gradually pushed back until I was able to expose the back of the bladder to the point where the ureters entered it. They were tied and cut on both sides. The pubocystic ligaments were then cut and some bleeding points tied. After the seminal vesicles and prostate were dissected free from the rectum, I found I had reached the point to which I had worked up through my perineal incision. The bladder was then wholly separated from its attachments. A large tube was carried out through the perineal wound to drain the pelvis. Other tubes were introduced from above and the wound closed.

The patient has made a very good convalescence and is now practically ready to go home. There have been one or two attacks of pain low down in his left side, accompanied with temperature, that I think may be due to a little section of ureter that was allowed to remain on that side.

As I see them, the important points of this operation, which is as yet uncommon, are these:

One should allow the end of the ureter to project beyond the skin of the loin some little distance. This certainly helps in fitting a collecting apparatus.

It may be an element in lessening the stenosis of the new ureteral outlet.

A considerable interval, we believe, three weeks or more, should elapse between the ureterostomy and the cystectomy. This is because pyelonephritis is almost sure to occur following ureterostomy, and this added to as serious an operation as cystectomy will prove fatal to a considerable number of these patients. The patients develop a certain immunity after the first severe attacks.

The operation, to my mind, should be done by the combined perineal and abdominal routes. In this, one begins below and dissects the urethra free as high as the prostate; one then begins above and carries the dissection down all about the bladder until he meets his first incision. If this dissection can be carried out without opening the peritoneum, it lessens the danger.

I believe that I left a small section of ureter on this patient's left side. It would be interesting to know whether the attacks of pain with temperature and local tenderness referred to this region were due to this little piece of ureter. If so, it would indicate the importance of removing it all at the time of operation.

DISCUSSION.

DR. J. B. BLAKE, Boston: Did you have any difficulty with the openings of the ureters,—was there any tendency toward stricture?

DR. CROSBIE: Not a bit. The right ureter I made out at the time of the operation was very much dilated, about the size of the thumb, and probably practically no urine was getting through from the right kidney into the bladder. Since the operation it runs freely on the right side.

The urine was of low specific gravity and has contained pus all the time. It had first a specific gravity of 1001 and it now is 1005. Apparently the right kidney is getting back some of its function.

DR. F. S. WATSON, Boston: I am afraid I have spoken already far too often upon one of my favorite projects, which is again suggested by the case just reported by Dr. Crosbie, but if you will forgive me, I will say just a word with regard to it once more.

Dr. Crosbie has followed the example of all but one or two of those who have adopted the plan of doing total cystectomy, which I proposed in 1905 for the first time. That is to say, he has adopted the most important part of my plan, which is that of dividing the operation of total cystectomy into two stages, but has substituted ureterostomy in the place of bilateral nephrostomy which I originally counselled as being preferable to it.

I received a letter from a gentleman in Philadelphia not long since, who tells me that he has followed my plan as it was proposed and that he has had a very successful result with it. His patient was operated on one year ago and is in good condition up to this time. This is almost the only case in which the bilateral nephrostomy, which I urged to be done as the preliminary operation in order to divert the urinary secretion before attacking the operation of total cystectomy, has been done, so far as I can learn.

My preference for the nephrostomy preliminary operation was based upon the knowledge that we had at that time, and have still today, that the kid-

ney is less liable to become infected with the broad, direct, free drainage that it offers, than it is in connection with the operation of ureterostomy, and, moreover, if infection does occur in the presence of well arranged and sufficiently free nephrostomy operations, it does not result harmfully to the patient, or in any case it is far less likely so to result than is the operation of ureterostomy, the drainage channel supplied by which is liable to become narrowed or occluded by adhesions, by bends in its course, and is in any case less free than is that of the nephrostomy drainage.

Both of the operations are easy of performance in the great majority of cases. I have always fancied that the preference for the ureterostomy was owing to its being the more readily performed of the two, which it is in my experience.

I am gratified however, to know as experience accumulates in the performance of total cystectomy in two stages as I advised and in the abandonment of the rectal implantation of the ureters in connection with it, which was the usual method employed formerly, that my prediction, that the mortality of total cystectomy would be greatly lessened if my plan were adopted, has proved true. In so far as the operative mortality is concerned, I have not seen reported as yet an operative death since the two-stage method has been put in operation. I still cling fondly to my preference for nephrostomy instead of any form of ureterostomy, but so far as this feature of my plan is concerned, I am open to conviction, and will gladly yield this point of the plan if I shall be proved to have been mistaken in the view I took of it.

I have shown the patient to this association on one occasion who has been wearing the apparatus which I devised for receiving the urine flowing from bilateral permanent renal fistulae. I will merely add now that he is still in excellent health in the eighteenth year following the first operation which was done.

DR. H. CABOT, Boston: We have had a little experience with the question raised by Dr. Watson as to the preference being given to nephrostomy over ureterostomy. I did three cases of nephrostomy and then I abandoned it, I will frankly say because mine were not successful. The results to the kidney were so certain and so absolutely damaging that I had to abandon it. My difficulty was this—the kidney under reasonably normal conditions is a very movable organ. The tube placed in the kidney is very apt to become fixed. As a result it becomes withdrawn from the renal pelvis and extensive, damaging and general infection of the kidney will occur. That has been the difficulty which I have been unable to overcome, the accurate fixing of the tube in a normal renal pelvis. There is no difficulty in a dilated renal pelvis. Therefore, the mere management of a nephrostomy with a normal kidney has seemed to me highly difficult on its technical side. If you do get efficient drainage of the renal pelvis through the kidney substance, the future integrity of the kidney is better secured than by ureterostomy, but I have been unable to carry it out technically.

Ureterostomy is open to the objection that it opens the lymphoid channels to the kidneys by the ureter. It is demonstrated experimentally and clinically with us with considerable regularity. Our prettiest case was a man in whom ureterostomy was done for cancer. After ten days a little redness of

the skin about one ureter was observed. From that a colon bacillus was obtained. Two days later he had fever and colon bacilli were obtained from the corresponding kidney, demonstrating the ascension of the process in the wall of the ureter. This has been demonstrated also with the coecus, though I think the bacillus follows the lymphatics more readily than does the coecus.

If a technique can be worked out that will satisfactorily drain the renal pelvis through the kidney, I believe that Dr. Watson's position will be entirely secure.

DR. R. F. O'NEIL, Boston: In line with Dr. Crosby's case I should like to mention again the case I reported at the last meeting. A case of malignant disease of the bladder in which double ureterostomy was done as a palliative measure for the relief of urinary symptoms. The second operation of removal of the bladder could not be done, as I was able to demonstrate at the first operation that the disease had gone beyond the bladder and the glands along the spine were involved.

There was no difficulty whatever about the ureterostomy. The ureters were exposed at the pelvic brim, freed towards the bladder and up to the kidney. They were divided low down. The lower end ligated and the upper brought out through a stab-wound in the back at a point previously marked. These were left protruding about one and one-half inches beyond the skin. They did not slough, and five weeks later were trimmed off close to the skin. Immediately following this a colon bacillus infection of the right kidney occurred. This ureter was dilated as a result of the pressure of the growth and was, I think, cut off a little too short. The infection subsided but never disappeared. The ureterostomy worked well up to the patient's death from his disease, a few months after the operation.

DR. A. L. CHUTE, Boston: In regard to these two operations, nephrostomy and ureterostomy, I recently have had a case of each. The first was a woman of thirty with an absolutely destroyed, tuberculous kidney on her right. On her left she began some weeks before to have attacks of colic with vomiting and later, signs of uraemia. A thickened ureter could be felt below, on her left. The urine was very pale, but that taken from the left pelvis showed little change. It was my opinion that I had to do with an ascending, urinary tuberculosis on the left side; that this process was beginning below with a thickening of the ureter which was so increased at times as utterly to shut off her urine, causing an obstructive anuria. During these attacks she had first colicky pain and temperature due to the obstruction, and later, vomiting, headache, etc., due to the toxemia. I could see nothing to do to relieve her but to do a nephrostomy, which I did, in May or June of last year. She came into the hospital within a week rather used up following an influenza. She has improved in color, in appetite and in weight. She has had no further attacks of colic or vomiting. Her loin sinus is of little trouble during the day, but at night we have as yet devised no satisfactory means of keeping her dry. As yet there is no sign of any decrease in size or increase in the lumen of the diseased ureter. I had hoped that the complete rest given the ureter, so far as function is concerned, would lead to improvement so far as the tuberculosis was concerned; but there is no evidence of this as yet.

The double ureterostomy was done about two

months ago on a woman in her fifties. This was intended as preliminary to a total cystectomy for cancer of the bladder. The patient had considerably dilated ureter on one side. She had a sharp pyelonephritis following operation and then faded away, dying about two weeks after the operation.

Dr. G. G. SMITH, Boston: I might say just a word about the nephrostomy to which Dr. Cabot referred.

The difficulty there was, that I did not get the tube clear into the pelvis of the kidney. On one side it was all right, but on the second side I was in too much of a hurry. I think I stripped the mucous membrane lining the pelvis so that my finger seemed to be in a free cavity, whereas, it really was not.

Autopsy showed that the tube on that side went through the cortex and then lay occluded by mucous membrane so that it did not drain the pelvis at all. There were focal abscesses in the kidney. I think that is probably the reason the man died.

A CASE OF DIVERTICULUM OF THE BLADDER.

Dr. J. D. BARNEY, Boston: The specimen I wish to show you is that of a diverticulum of the bladder, interesting because of its unusually large size. It was from a colored man of 56 years old. He was referred to me early last February, with the story that up to last January he had had no urinary difficulties of any sort. He had a long venereal history. In January he had sudden acute retention, and from that time until I saw him he had had to be catheterized frequently. His bladder was distended up to the umbilicus. With a soft rubber catheter I drew off about three pints of urine like pea-soup, loaded with pus and blood. I tried to cystoscope him, but had much difficulty getting the instrument into his bladder. There was some bleeding, and I could put fluid in but could not get it out. This made me suspicious that I might have gone through his bladder into the peritoneal cavity. Such was not the case, for, after removing the cystoscope, I was able to empty the bladder fairly well by a silver catheter.

I sent him to the hospital and made two or three more attempts with the cystoscope, but with little success; all I could see was a red blur, and the passage of the instrument as well as the removal of fluid from the bladder was very difficult. Finally, I introduced a silver catheter and found that it went readily into a large cavity in the median line which I could empty and wash out easily. In the meantime, we had noticed a smooth, round, firm mass the size of a grape fruit, low down on the right side of the pelvis. By withdrawing the catheter I was able, after a little manipulation, to pass it into this second cavity from which I was able to draw off about fourteen ounces of thick, dirty urine. After emptying this sac, I could feel a distinct grating of calculi. I made a diagnosis of diverticulum, with calculi, but could not gather any more information from an x-ray.

Operation was performed with gas-oxygen anesthesia. I opened the bladder suprapubically and found an opening on the right side, rather high up, which admitted my forefinger. This cavity had apparently not been drained, in spite of the fact that we had tried almost for a week with various kinds of constant drainage apparatus. I packed the cavity tightly with gauze, pushed back the periton-

eum and dissected it out entirely extra-peritoneally. This was not difficult, except in spots where there were firm adhesions, especially low down against the pelvic wall. Previous to this I tried to find the ureteric orifice on that side but could not. During the dissection the ureter showed up, lying between the diverticulum and the bladder, and I had no trouble with it. It emptied normally into the bladder. Having dissected the diverticulum down to a small neck connecting it with the bladder, I cut this off and closed the opening with a double row of sutures.

Convalescence was uneventful, and the suprapubic wound was closed. The urine was quite clear, but unfortunately the patient can urinate only an ounce or two, after which twenty or thirty ounces can be withdrawn. This retention seems to be a not unusual occurrence as a result of a diverticulum; probably owing to a lack of tonicity.

It may be that the retention is due to an enlarged prostate. I noted at the operation that his prostate was slightly enlarged, but as he was having all that was good for him, I decided not to take it out. Whether the removal of his prostate will relieve his difficulty remains to be seen. We are inclined to let him go home to see how things will work, instructing him to catheterize himself when necessary.

The specimen which I will show you was stuffed with cotton and then hardened in formalin. A small piece was taken out for examination. We have no detailed report as yet, but there appear to be two or three muscle layers which would indicate the congenital origin of this diverticulum.

DISCUSSION.

Dr. F. S. WATSON, Boston: I feel inclined to congratulate Dr. Barney because of his having refrained from disturbing the prostate when he removed the diverticulum of the bladder which he has shown us. I say this because of a singular and so far as I can learn unique experience of mine in which the prostate and a diverticulum played the principal parts. The truth of the statements I shall make about it will be vouchsafed by Dr. Blake who was with me when I did the operation.

The incident was as follows: I was doing a perineal prostatectomy one day, and had reached the point of the operation when the prostate, which I should have said was not a very large one, was enucleated and lying free within its sheath. I was about to draw it toward the outer wound with my finger tip when it slipped from under it and fell into the bladder. This did not disturb me, because I knew that I could readily seize and withdraw it with a pair of forceps. I put the blades of the forceps into the bladder and began my search for the gland. I continued it for five full minutes without finding the runaway anywhere within the bladder. I put my finger into the bladder and four minutes' unavailing search was added to that which had preceded. I diligently, but with lowered spirit, then examined the rectum. I became convinced that I was the victim of witchcraft. However, I once more made a digital exploration of the bladder and as I was again about to retire from it profoundly discouraged, the tip of the finger slipped into the mouth of a diverticulum. Within it, snugly ensconced lay the wandering prostate. After some trouble I succeeded in seizing it and extracting it from its lair. The episode was closed.

DR. R. F. O'NEIL, Boston: Was the Wassermann reaction done?

DR. BARNEY: We went all over the venereal history, and it was negative.

A VESICAL CALCULUS FORMED ABOUT A LIGATURE FOLLOWING AN OPERATION FOR HERNIA.

DR. A. L. CHUTE, Boston: I have here a bladder stone which I removed yesterday. It has a piece of ligature attached. It was found, not at the base of the bladder, where one ordinarily sees stones, but well up on the lateral wall. The patient, a man of thirty-five, had a hernia operation two years ago and following this he had urinary symptoms, pain, frequency of urination, and at times a slightly bloody urine. He was seen by one or two men who felt sure his symptoms were due to prostatic trouble. They made cystoscopic examinations but evidently examined only the trigone, which in this case was not the most important part, for I found this stone clinging well up on the right lateral wall. Its position at once stamped it as either a stone formed on a ligature, or one held in a diverticulum. The history of an operation made the former the more probable. When I opened his bladder yesterday, the stone was held definitely in place. Finally I hooked into the little loop of thread and broke it so that I could pull the rest of the loop out, and removed the stone which, you will see, is formed about a bit of linen thread.

It is the second stone of this sort that I have seen. They bring up an interesting question as to whether these ligatures on which they form penetrate the bladder wall at the time of operation, or whether they migrate into the bladder later, as foreign bodies occasionally do. My feeling has been that these ligatures probably migrate into the bladder. Most men, I think, do not agree with me, but feel that the suture penetrates the bladder at the time of operation. Which is right I do not know.

DR. G. G. SMITH read a paper entitled "Experimental and Clinical Observations on the Blood Pressure in Spinal Anesthesia."*

DISCUSSION.

DR. C. O. COOKE, Providence: I should like to report a case of spinal anesthesia in which there was a fall in blood pressure of 155 m.m. The patient, a man of 65 years of age was operated on for stones in the bladder. The blood pressure before administration was 225 m.m. He was given 6/100 gram stovain and 6/100 gram glucose. Three minutes afterward, the man became unconscious and began to snore as if under general anesthesia. The blood pressure was 70 m.m., a fall of 155 m.m. in three minutes. It remained around 70 to 90 for 50 minutes, then gradually began to rise. In one hour and 15 minutes it had reached 140. The patient after that had no untoward symptoms. He was given 1.2 c.c., of this solution, which would be 6/100 gr. of stovain and 6/100 grams of glucose.

DR. H. CABOT, Boston: In regard to clinical knowledge, there are certain facts which seem to me clear, but on which I think we want further data. It has been striking in my personal experience that the comparatively young individuals to whom spinal anesthesia has been given for operations on the extremities or on the perineum including cystoscopy,

have all done extremely well. The blood pressures which have been done in a number of these cases have not shown very great drops. The older individuals, particularly those upon whom operations have been done above the symphysis, have shown the great drops in blood pressure and have given the outward and visible evidence of shock. I have been unable in my own mind to avoid the conclusion that these great drops bear a direct relation to the condition of the arteries, being related either to arteriosclerosis or to a weak heart, or both. The explanation of that I am not prepared to give, unless it be that the compensating mechanism which avoids the over distention from paralysis from the splanchnic vessels is better managed by those with limber vessels than those with stiff vessels. That explains why a large group of cases, chiefly gynecological, have uniformly done well, and why a group of our cases, for instance, of prostatectomy on people of advanced life, have done badly.

Dr. Smith has carried this work a little farther than I have seen it carried before, and it seems to me an extremely valuable piece of work in a field where we have been groping in the dark, where there has been tendency to publish good results and withhold bad ones. I do not think spinal anesthesia is either highly desirable or highly undesirable, but I think we shall come to rely on it as a safe anesthesia in certain cases.

DR. E. L. YOUNG, JR., read a paper entitled, "A New Preparation for Pyelography Illustrated."†

DISCUSSION.

DR. H. BINNEY, Boston: After having read last year about the use of silver iodide, I did some experiments of injecting the kidney pelvis in rabbits, using a 5% suspension of silver iodide in alboline. Examination post mortem showed at varying numbers of days after injecting no evidence of irritation and the material passed out of the pelvis pretty rapidly. I later tried a suspension in an emulsion of quince seed suggested by the originator, and found, as Dr. Young says, that it becomes contaminated by fungus growth, and oxidized. I did not try it on a human subject as it seemed unwise with such a thick preparation.

I congratulate Dr. Young for having worked out such a satisfactory preparation.

DR. CHUTE: I have the pleasure of introducing to you Dr. Paul W. Pilcher of Brooklyn, N. Y., who will read a paper entitled, "Transvesical Prostatectomy. A Discussion of Some Unsettled Points in the Preparation for and the Technique of the Operation."‡

DISCUSSION.

DR. W. W. TOWNSEND, Rutland, Vt.: I would like to ask Dr. Pilcher if he would go a little into detail with regard to the estimation of the leakage through the drainage tube.

DR. PILCHER: In suturing the Pezzar catheter into the suprapubic wound, it is found that there is no leakage around it and that all the urine is passed through the Pezzar catheter; therefore, any test of renal function may be made and the entire amount of urine passed in a given time collected and an accurate test made.

DR. G. G. SMITH, Boston: What anesthesia do you use?

* See JOURNAL, Vol. clxxii, p. 539.

† See JOURNAL, page 494.

* See JOURNAL, page 502.

DR. PILCHER: The preliminary operation is done under novocain anesthesia. The second operation is done under ether anesthesia given by the drop method with infiltration of the prostate and urethra with the novocain solution.

DR. H. CABOT, Boston: I do not want to let this occasion pass without making some comments. Dr. Pilcher seems to me to have carried farther than anybody else that I know, certain steps of this two-stage operation. The two-stage operation (I don't know where it originated), as it was commonly done by a good many men consisted of opening the bladder and leaving the patient soaking wet for two or three weeks. Now this operation of Dr. Pilcher's is on an entirely different basis and interested me because I think it should be compared with the cases which we drained above the bone by puncture, which was described with illustrations by Dr. Wishard in 1888, and has been used by him ever since.

This, it seems to me, has some of the advantages of Dr. Pilcher's procedure. It enables you to get suprapubic drainage through a good size catheter. It does not give the walling off of the tissues so that secondary infection will not take place. We have used that procedure in a small number of cases, almost entirely those which have over-distended bladder, in which the urine is uninfected, and in which we dislike the certain infection following urethral drainage. These we have punctured and put in a catheter, and later, at the time selected very much as he does, have operated by an ordinary suprapubic operation. The only flaw in these cases is that they heal slowly. I confess that with some of the patients that we see, I fear that my abbreviated fingers would be unable to reach the prostate. Some of them have an abdominal wall about four inches thick. Perhaps I could borrow an extension from Dr. Pilcher. This preliminary walling off of the tissues introduces an element which I have never before mentioned, and it seems to me interesting.

Again, Dr. Pilcher's paper brings out that bad time, about four or five or six days after beginning drainage, with everything going down. I have come to believe that that represents acute pyelonephritis generally with the colon bacillus, a phase through which most of these patients have to go, and it seems the thing which we achieve by our drainage. This sounds ridiculous but it is true, and it produces an immunity which protects him. This immunity is probably short-lived. It has been our experience that we could demonstrate the onset of this infection in the urine, and the slow at first, then rapid, decline of the kidney function as the infection in the kidney takes hold and develops. Whether or not there is any avoiding that process of voluntarily infecting the kidneys and letting them secure their own balance is an interesting point to be developed in the future. If there is any way by which we can protect these patients against infection, it seems to me it would be interesting. I shall be tempted to try this two-stage method of Dr. Pilcher's.

DR. J. W. KEEFE, Providence, R. I.: I have had some experience with this two-stage method advocated by Dr. Pilcher, and I can say that I have been very much pleased with the progress of most of the cases. I have used the local anaesthesia during the primary operation, novocaine about 1/400 and adrenalin. I have felt that the combination was a little bit better than the novocaine alone.

It is just as Dr. Pilcher has said,—when you use a Pezzer catheter you can have all the urine passed into a bottle either attached to the dressing or placed at the side of the bed. In a few cases I use the ordinary drainage tube, but I do think the Pezzer catheter is more desirable.

It is important not to introduce your tube very far into the bladder. If it goes but a short distance into the bladder there is much less irritation.

I was quite surprised to find how readily one could, after the wound was partially healed, pass a finger through, where the drainage tube was, and enucleate the prostate, and then with a small stone forceps grasp the prostate and remove it.

My experience in prostatic work has given me an opportunity to try several different methods. First, from doing most of our work through the perineum and doing median perineal operations we remove the prostate by that route. Then I saw Dr. Young do some of his work, and I concluded that that was a very good way. In some cases it worked beautifully. Then I saw Dr. Mayo do some of his perineal prostatectomies, using his knife to make an incision through the mucous membrane. There are types of cases where that works very well, and it was surprising to see him, after doing a hard day's work, at the close of the day do a couple of prostatectomies in a very short time. In former times when we had those large wounds following suprapubic operations, and we found the wound sloughing and encrusted with phosphatic material, I had the impression that the suprapubic operation was a pretty serious matter, but as the suprapubic operation is done today according to this method of Dr. Pilcher, where you open your bladder and put your catheter in and close it properly, you have a different problem.

Dr. Cabot is just right about what he said with reference to the patient becoming immune. I think when we make this incision in our suprapubic primary operation, the patient does get a certain reaction from that, and I think we really do immunize the patient. So when we go in the second time to enucleate our prostate I think the patient is in a better condition to withstand the trauma. It seems at times one could enucleate the prostate at the first operation so easily that there is a temptation to do it. In one case I think of, which should have been a two-stage operation, we concluded we would take it out in the first stage, and got away with it.

Some years ago I opened the bladder by mistake in doing an abdominal operation, and the other day I opened the peritoneum in doing this first stage operation and it seemed to me that it was not possible to do it. So I was glad to see that Dr. Pilcher had clearly drawn out the fact that the peritoneum can be very near the pubic bone. In this particular case, the peritoneum bulged up so that it was very prominent.

We must bear in mind that we must not criticize the other fellow too much, but I have been impressed with the fact that Dr. Pilcher is on the right track.

DR. J. H. CUNNINGHAM, JR., Boston: I do not remember having heard a paper on the subject of prostatectomy that has held my interest more than the one Dr. Pilcher has given tonight. The various features that he has spoken of are all practical steps, and the reasons for their employment seem to me sound in every particular. The method of suprapubic drainage with the Pezzer catheter is one that I have employed for several years and to my mind

is the ideal method. The preoperative charts are most interesting and instructive. I think we have all observed the clinical features which they graphically portray, and I believe such charts are of much value. The Hagner bag with a catheter passing through it appeals to me strongly, for being one who still does the perineal operation, I have been working on this same idea to control haemorrhage and still have perineal drainage. This modification solves my problem.

DR. G. A. MATTESON, Providence, R. I.: I wish to simply mention a means of extemporizing a Hagner bag by taking a glove finger and attaching it to a rubber catheter by means of an elastic band. This seems very thin, and insecure on account of its thinness, but I have found by testing that it stands all the pressure that is necessary, and serves the purpose very satisfactorily. I have used it in several instances with entire success.

DR. A. L. CHUTE, Boston: I want to express my appreciation of Dr. Pilcher's paper, in which I have been especially interested, since I have been impressed with the importance of doing these preliminary operations for some time. I don't feel, however, that a preliminary cystotomy is nearly as important as Dr. Pilcher does, in that I do not believe it is necessary in all cases. I think that when you need to drain these cases as a preliminary step, when there is a question of renal sufficiency, it is wiser to open them up widely and establish adequate drainage, rather than to attempt intermittent drainage by means of a catheter introduced through a trocar. I assume that the man with a large residual of uninfected urine—the dangerous type of patient—is practically sure to be infected by any method by which you drain him. The urine is an especially favorable culture medium if, due to renal back-pressure, it contains a slight trace of albumin. The wider the bladder opening, the less intermittent the drainage and, hence, the less probability of kidney infection—the great danger in these cases. Likewise, constant and free drainage tends to lessen the congestion about the prostate, thus lessening the probability of troublesome bleeding at the time of enucleation. I confess that I am less troubled about the bleeding than many, since the simple method which I have used for many years of packing about a soft rubber catheter effectually controls hemorrhage.

CLOSING DISCUSSION.

DR. P. W. PILCHER, Brooklyn, N. Y.: I appreciate very much the fine things that have been said by the members about my paper. It is especially pleasant to me to have the technic of this two-stage operation accepted by the New England men, because I know how conservative they are in their prostatic work. Our main object in developing this technic has been to shorten the period of anesthesia, to lessen the surgical shock, to control the hemorrhage, to remove all obstructive disease and perform the operation in such a way that the patient will remain dry after his operations, and be up and about after the first 24 hours. This we have been able to accomplish by doing the operation in two stages, feeling our way in each case and using the Pezzet catheter, which entirely controls the output of the urine.

The most interesting development during the past few months has been the education of the bladder

after the drainage tube has been removed and substituting the Pezzet catheter within four days, we are able to have the patient resume his urination, controlling any obstruction by the Pezzet catheter safety valve.

It is remarkable in our experience how completely the suprapubic wound heals, even in the presence of an infected bladder, without any infection of the prevesical space when the technic has been followed out. It will be interesting to see if others obtain equally good results following this technic.

CLINICAL CONFERENCE OF THE NEUROLOGICAL INSTITUTE, NEW YORK.

REGULAR MEETING, MAY 13TH, 1915.

DR. J. RAMSAY HUNT in the Chair.

A CASE OF PLURIGLANDULAR DISTURBANCE OF THE INTERNAL SECRETIONS.

DR. T. S. KEYSER presented a patient from the First Division illustrating the profound effects of an apparently purely functional disturbance of the internal secretions.

There are certain definite symptoms which have been recognized for many years as being due to either hypersecretion or hyposecretion of one of the ductless glands. For example: Caleb Hillier Parry in 1825 described eight cases of enlargement of the thyroid gland in connection with enlargement or palpitation of the heart, exophthalmus, agitation, and mental distress; Sir William Gull in 1873 wrote his classical work on myxoedema dependent on the partial or complete cessation of the thyroid activity; Addison in 1855 wrote his monograph on *The Constitutional and Local Effects of Disease of the Suprarenal Capsules*; and in 1886 Pierre Marie described with remarkable completeness the condition to which he gave the name of *acromegalia*.

However, during recent years the subject of internal secretions has acquired renewed interest from the fact that numerous cases which do not present any definite clinical entity are doubtless the result of a purely functional disturbance of one or more of the ductless glands. The interrelation of the various glands is so intimate that usually there is evidence of abnormal secretion of several, but practically always one gland is primarily at fault. If the anamnesis is taken from this standpoint a condition, which otherwise seems entirely without cause, can be explained step by step, thus showing quite clearly why at a certain time a patient develops certain symptoms. For example, a woman may give a history of irregular, painful menstruation and later suddenly begin to have attacks of severe migraine or even of epilepsy. In such a case it is quite evident that there is some disturbance of the gonads primarily. However, the pituitary gland is able to compensate temporarily for this but sooner or later, due to the strain of overwork, it becomes congested and thus causes the migrainous or epileptiform attacks.

The following case is presented in order to attempt to show why a woman, apparently in perfect health, suddenly develops an illness so marked that one would scarcely recognize her as the same individual.

The patient is a nurse, aged 31, who was admitted to the hospital on February 15th, 1915, complaining of insomnia, headache, paraesthesia and nervousness.

Until the onset of the present illness she was an unusually healthy, energetic and optimistic individual. There are, however, three important facts in the past history: first, she grew up very rapidly, attaining the height of five feet seven inches at the age of 15; second, menstruation began at 11 years and occurred regularly, without undue pain and with normally profuse flow until the present illness was well established; third, before or after each menstrual period she complained of nausea and temporal headache, always unilateral, followed after 15 to 18 hours by vomiting, with complete relief of the headache. Her mother and five of six sisters also had the same symptoms associated with menstruation.

In 1910, she graduated from St. Vincent's Hospital with a very good standing. Shortly after this, she became night supervisor at the New York Foundling Hospital. For two years she fulfilled her duties with the greatest efficiency, always active, energetic and much interested in her work. Except for the headaches associated with menstruation, she was well until 1912.

The present illness began suddenly in April, 1912, with insomnia. After four days of sleeplessness, she began to take various hypnotics, with little effect. When she did go to sleep, she had constant worrisome frightful dreams, from which she would awaken feeling unrefreshed. After a few weeks she became nervous, restless and depressed. She became inefficient in her work, and in a month had to give up her position at the hospital. Since this the insomnia has persisted. She gradually became more and more indolent, careless about her personal appearance, and unable to do any work at all. Before the illness began she perspired freely on moderate exertion, since then she does not perspire at all, even in an electric bath.

After several months she began to gain weight, although she says she ate less than before. Her normal weight had been 170 lbs. By July, 1913, she weighed 257 lbs.—a gain of 87 lbs. Since then her weight remained about the same. Not only has there been increase of adipose tissue, but the features have increased in size according to the statement of the patient and her friends.

In July, 1912, she began to have tight drawing headaches in the occipital region. In the morning she would feel nauseated, but never vomited. A year later she complained of a constant numb dead feeling, and a sensation of pins and needles over her entire body, but especially about the neck and shoulders. Soon after this, twitching movements of the neck and shoulders began, which she is unable to control. She thinks these movements are due to the annoying sensations which she endeavors to relieve in this way. She complains also of frequent nocturnal urination. For the last six months, menstruation has occurred every two or three weeks. The flow is rather scanty. At night during the last year she has had hot flushes. At no time has she noticed any disturbance of vision, nor has she vomited.

In comparing the patient's appearance with that indicated by a photograph taken in 1908, one is much impressed with the striking contrast. At that time she presented the picture of a normally developed, healthy, alert, composed woman, with a tendency to adiposity. At present she is fat, indolent,

careless about her personal appearance and she frequently twists her neck and shoulders, in order, she says, to relieve the tightening sensation of the skin. The skin is coarse, puffy, dry and greasy. There is no abnormal pigmentation, except a few pigmented naevi about the shoulders and the face. The hair of the head is dark, fine and shiny, and devoid of curls. The pubic and axillary hair are normal. The eyebrows terminate abruptly at the outer quarter. There is a slight growth of hair on the upper lip, but no abnormal development of hair on the trunk or extremities.

There is a general deposit of flabby adipose tissue, especially marked about the face, neck, shoulders, abdomen and hips. The breasts, which formerly were well developed and firm, are now flabby and pendulous, and seem deficient in glandular tissue. The external genitalia are very small.

The head and face are very large, but the cheek bones, and lower jaws are not unduly prominent. The teeth are not spaced. The cranium measures 13½ inches in circumference. The hands and feet do not appear enlarged. The patient is 5 feet 7 inches tall, the same as when she was 16 years old. The nails are stumpy and ridged up and down. The x-ray of the cells tursica is entirely negative.

The eyes are slightly prominent, but the usual signs of exophthalmus are absent. The motility of the eye-balls is normal, except that on looking upwards the right eye-ball turns slightly inward. The pupils are equal, regular, and react normally. There is no disturbance of vision, nor retraction of the visual fields. The fundi are normal. There is no evidence of involvement of the other cranial nerves, or of the motor and sensory tracts of the cord.

The heart is not enlarged and no murmurs are heard. The pulse is regular, but rather rapid, varying in rate from 80 to 100. The blood pressure showed marked irregular variation,—at times as low as 120 and at times as high as 160. The temperature is usually slightly subnormal. The blood and urine are entirely negative. The patient was given levulose in increasing doses up to 500 grams without the appearance of sugar in the urine. The normal sugar tolerance for one of her weight would be 445 grams.

The history of rapid increase in weight, absence of perspiration, and polyuria, together with the character of the skin, the disposition of the fat, and the dystrophy of the mammary glands and external genitalia, subnormal temperature and reduced metabolism, is the typical syndrome of hypopituitarism associated, doubtless, with disturbance of the thyroid secretion.

However, there are several other facts in the case which bring up the question of whether the pituitary dystrophy is primary, or whether secondary to a disturbance of other internal secretions.

The patient first showed a precocity in her sexual development. At the age of 11 she began to menstruate, and showed the development of a girl 14 or 15. She also grew very rapidly between the age of 11 and 15. The headache and vomiting, although apparently a hereditary condition, might be due to some abnormality in the secretions of the genital organs, giving rise to congestion of the pituitary secondary. Menstruation occurred regularly for 20 years, but during the last four months every 2 or 3 weeks. In a woman of 45, this alone would suggest the arrival of the menopause.

The present illness began with insomnia, followed in a short time by a mental state somewhat simi-

lar to an involutional psychosis. These symptoms would hardly be due to the hypophysis or thyroid, but could be quite consistent with the climacteric. The paraesthesia and hot flushes also point strongly to the ovarian secretions.

The variable blood pressure, the pigmented naevi, and the hirsuties would also suggest involvement of the suprarenal glands.

In this case the gonads are considered to be primarily or constitutionally at fault. Until the onset of puberty the patient was never sick, not even having the ordinary diseases of childhood. This fact, together with the absence of any physical signs, such as spaced teeth, would show that all the ductless glands were functioning perfectly. However, menstruation began unusually early and was associated with severe headache and vomiting. Apparently the patient inherited a defective gonadal apparatus as her mother and sisters had the same difficulty. The pituitary gland, which is closely associated with the sexual, at once gave evidence of being affected at the menstrual periods, giving rise to migraine and vomiting, and, probably as a result of hypersecretion causing rapid growth during the early years of puberty. Aside from this however, nothing of a serious nature manifested itself until the age of 28, when it seems that the sexual apparatus which for 18 years had been functioning regularly although abnormally, became exhausted and, as a result, put still further strain on the pituitary. The latter, unable to compensate for the gonads, caused a general break in the balance of all glands of the internal secretions, thus giving rise to the numerous symptoms and signs which can be accounted for only on such a basis.

ACUTE CHOREA OF THE INFECTIOUS TYPE, RELIEVED BY LUMBAR PUNCTURE.

DR. WALTER TIMME from the Third Division showed a typical case of Sydenham's chorea which had begun six weeks previously, and had rapidly progressed in severity until the child was admitted to the New York Neurological Institute five days ago. The patient, a girl of eight years, showed upon admission all the usual symptoms in marked degree. Her choreiform movements involved the whole body to such an extent that she could neither stand nor walk. Her speech was affected, she was unable to hold anything in her hands, and she was emotionally much disturbed, irritable and depressed by turns. She had no endocardial murmur although the heart's action was rapid and overacting. Her previous history included scarlet fever and measles a few years ago and a slight tonsillitis with febrile disturbance just before the present attack began. Upon admission she was so choreic that boards had to be placed on either side of the bed to prevent her from falling out during the spasmodic movements. No medication of any kind was given for forty-eight hours and the condition persisted as at first. Then spinal puncture was done and about 8 c. c. of fluid removed which proved to be normal. It flowed out under pressure, however, in a fine stream although the child was lying prone. A few hours after this procedure the choreiform movements became less general and in a day they remained apparent only in the hands. In three days they had practically disappeared, the child felt well and began to walk. In five days she was discharged with only the faintest suggestion of choreic twitching in the hands. So that in five days following

lumbar puncture, a most intensely developed genuine chorea succumbed; which under former treatment of Fowler's solution, salicylates, and rest, would have taken as many weeks at least. Passini (*Wiener Klin. Wochensh.* xxvii No. 42) reports five cases that he treated by this method, three of which were cured. These three had all been acutely affected for several weeks following rheumatic attacks and were free from fever. The fluid was uniformly at a fairly high pressure and was sterile.

The unimproved cases were all of longer standing and the fluid was not under undue pressure. It would seem that we have in this therapeutic measure one that will prove of great value in selected cases of chorea of the infectious Sydenham type.

The Third Division of the Institute will shortly present a series of these cases.

A CASE OF UNILATERAL ASCENDING PARALYSIS.

DR. J. RAMSAY HUNT presented from the Second Division, a Russian Jew, 43 years of age, who was admitted to the Neurological Institute on April 12th, 1915. He is a worker in metals, chiefly brass and lead, but has never had symptoms indicative of lead poisoning. He denies lues and has never indulged in alcohol or tobacco. There is no history of injury. His health, prior to the onset of the disease from which he now suffers had been excellent and he can recall no previous illnesses.

The family history presents several points of interest and is as follows:

His father and mother were first cousins and had 5 children: The first a girl, is living and in good health at the age of 44. Two brothers aged 36 and 25 respectively are living and well. One sister is now 37 years of age, and is a patient of the New York City Home. She is paralyzed and cannot walk. Her symptoms began at the age of 30 and were gradually progressive. (Dr. Climenko reports that she has a unilateral local lesion in the cervical region with spinal hemiplegia and contralateral sensory disturbances).

The mother is living at the age of 73 and is in good health. The father is said to have had a lameness of one leg and to have walked with a cane, but the account of this trouble is obscure, and it was probably arthritic and not spinal in origin.

Onset: The first symptoms of the disease appeared 5 years ago and consisted of a weakness of the left leg. At the beginning, the weakness was chiefly noticeable in the foot and was accompanied by some stiffness of movement, so that the toe often seemed to catch and meet obstructions. This gradually progressed, ascending the extremity until finally the movements of the knee and the hip were also affected. For three years these symptoms were limited to the left lower extremity and during this time there were no pains or paraesthesias, but not infrequently the muscles of the leg would cramp and contract, which caused some pain, but rubbing the parts and a change of position would bring prompt relief. Such spasmodic seizures often occurred in the night and would awaken him.

Soon after the beginning of the illness, his sexual power began to fail and for the past three or four years he has been impotent, with, however, the preservation of libido. For the past two years there have been some slowness and delay on the act of micturition, but never any incontinence. He is also constipated. Two years ago, i. e., three years after

the onset of stiffness and weakness in the left leg, a similar disturbance became manifest in the left hand and arm. This appeared very insidiously, and as in the leg, progress had been slow and gradual. There were no pains or paraesthesias, simply slowness, weakness and stiffness of the movements. He is not conscious of any disturbance of speech or articulation, or of the movements of the neck.

He has at no time had headache, or vertiginous seizures or faints, and his eyesight is good.

Subjectively, the right side is perfectly normal, with the exception of occasional muscle cramps in the right leg and arm. Otherwise, he claims that this side is as active and strong as ever. There is some variation, apparently in the weakness of the left side, while the spastic paralysis from which he suffers is constant. He tires very readily and after walking $\frac{1}{4}$ to $\frac{1}{2}$ a mile he must rest. After a brief rest he is able to continue. On some days he is able to walk better and farther than on others. The sensation induced by walking, however, is one of pure fatigue and there are no pains, paraesthesias or painful cramps of the extremities. He chews and swallows with perfect ease and there is no diplopia and no impulsive emotional outbursts.

Examination. He stands perfectly well alone and on a narrow base, on closure of the eyes there is no swaying. The attitude is somewhat hemiplegic and the gait is typically so, carrying the arm flexed and swinging and dragging the leg in the typical hemiplegic manner. The facial innervation, voluntary and emotional, shows a slight weakness of the lower branch on the left side. The tongue is protruded in the median line, no fibrillation or atrophy of the muscles of the tongue.

The pupils are equal and react promptly to light and accommodation. The ocular excursions are normal, no nystagmus. Dr. HOLDEN reports that the fields and optic nerves are normal. The innervation of the pharynx and muscles of mastication is normal. The palatal reflex is active and the jaw-jerk is active. The hearing and smell are normal and equal in the two sides.

The spine is normal in contour and in movement. There is no spinal rigidity and no pain on movement or jarring.

In comparing the movements of the arms there is some weakness and a distinct slowing of the movements on the left side. There is however, no tremor and no ataxia. The tendon reflexes including the periosteal reflexes of the upper extremities are exaggerated and especially on the left.

The left leg is weak and spastic; movements of the right leg are strong and free from spasticity. The knee jerks and ankle jerks are exaggerated on both sides, but to a much greater degree on the left. On the left side there is ankle clonus and an exhaustible patellar clonus both of which are absent on the right.

The Babinski and Oppenheim phenomena are typical and constant on the left. At times, the Babinski reflex is also elicitable by stimulation of the right plantar region, but it is inconstant. The Striampell phenomenon is present on both legs. The abdominal and cremasteric reflexes are usually absent on both sides. Occasionally faint responses were obtained on the right side. Associated movements were not demonstrable. There is nowhere any evidence of localized muscular atrophy or fibrillary twitchings. The general muscle-volume of the left arm and leg is less than that of the right.

The Right leg	measures	13½ inches.
Left	"	13 "
Right thigh	"	18¾ "
Left	"	18¼ "
Right arm	"	10¼ "
Left	"	9¾ "
Right forearm	"	10 "
Left	"	9½ "

There is no ataxia or tremor of movements of the lower extremities.

The general sensations, both superficial and deep, are quite normal.

The heart and lungs and abdominal viscera are negative. The examination of the urine, blood and cerebrospinal fluid by Dr. Kaplan are negative. There are no granular degenerations of the erythrocytes. (No lead on the gums). The Wassermann reaction of the blood and cerebrospinal fluid is negative, it contains no excess of globulin and only one cell to the cmm. Fehling's reduction is +.

Remarks. The case belongs to that rare clinical type which was first described by Dr. CHAS. K. MILLS as "*unilateral progressive ascending paralysis*," and caused by a unilateral degeneration of the pyramidal tracts. Later Dr. SPILLER demonstrated microscopically a degeneration of the pyramidal tracts in a case which began as unilateral ascending hemiplegia, later passing into triplegia. That this symptom complex may be simulated by diseases other than primary pyramidal tract degenerations has been shown by Patrick, (unilateral ascending paralysis in paralysis agitans) and by Potts in multiple sclerosis. Following Mills, Oppenheim has also indicated the possibility of unilateral, postero lateral sclerosis: viz: an ascending hemiplegia complicated by sensory disturbances.

I have observed unilateral ascending paralysis in a case that years later terminated in the clinical picture of amyotrophic lateral sclerosis.

The case just reported I regard as a primary lateral sclerosis with unilateral localization of the disease. Doubtless later, the other pyramidal tract will show similar involvement and the importance of such a case is to emphasize the possibility of a unilateral limitation in what is usually a bilateral and systemic disease.

Book Reviews.

Human Motives, by JAMES JACKSON PUTNAM, M.D., Professor Emeritus, Diseases of the Nervous System, Harvard University. Mind and Health Series, Edited by H. ADDINGTON BRUCE, A.M. Little Brown & Company, Boston, 1915.

Dr. Putnam describes the main purpose of this small volume to be the "focussing of attention on the aid afforded by modern psychology to the upbuilding of a really sound and practical philosophy of life." In the theory of psychoanalysis as promulgated by Freud and his followers, Dr. Putnam sees the broadest implications and finds in the theory not only a means of arriving at important facts in individual

lives but also the possible foundation, or at least support, of a philosophical system. Although always courteously expressed, he has little sympathy with the materialistic view-point. As he believes it, the material world must find its ultimate explanation in a world of ideas and vital energy. "Physics," he says, "can come to its rights only through metaphysics;" and again "The genetic method leads straight and of necessity to the philosophic method." On this general basis he studies motives and it need hardly be said that the book is broad minded, uplifting and widely suggestive. The chapter headings are as follows: I, Main Sources of Motives; II, The Rational Basis of Religion; III, The Psychoanalytic Movement; IV, Educational Bearing of Psychoanalysis; V, Instincts and Ideals; VI, An Attempt at Synthesis. We sometimes wish that Dr. Putnam were not so sparing of others' feelings and were less modest in the expression of his own well considered opinions, but it is evident that beneath his kindly words lies a conviction that he has a message for those of narrower vision. The book should be widely read especially as a philosophic expression of the significance of certain far reaching modern tendencies in medicine. The philosophic approach to medical problems is sadly needed and this Dr. Putnam supplies in this readable treatise on Human Motives.

Report of the Massachusetts State Board of Health. Boston: State Printers. 1914.

The recently published forty-fifth annual report of the State Board of Health of Massachusetts gives a record of the activities of that board for the year ended November 30, 1913. In the matter of antityphoid inoculation the following report is made:—

"During the year 21,014 ampoules of antityphoid vaccine have been distributed for use by the citizens of the Commonwealth, but of this number 10,526 ampoules were utilized by the militia. This immunization of the militia, affecting as it does a large body of young men in the prime of life, at an age peculiarly susceptible to typhoid infection and subjected, at the time of professional manoeuvres, at least, to increased exposure to polluted water supplies, cannot but have an appreciable effect upon the incidence of the disease.

There is every reason to believe, furthermore, that the practice of inoculation of nurses, inaugurated two or three years ago at a considerable number of training schools throughout the Commonwealth, has become increasingly prevalent, with undoubtedly beneficial effects."

The total number of samples of food and drugs collected and examined during the year was 9727. One hundred and sixty-one prosecutions were made in the various courts of the Commonwealth. Of these, 116 resulted in conviction, 2 were dismissed by order of the court, 1 dismissed for lack of jurisdiction and 1 not

pressed. Four thousand four hundred and ninety-three dairies were examined and the attention of 1543 proprietors and boards of health and of cities and towns called to objectionable conditions. The board received notification of 66,249 cases of infectious diseases. The fatality from typhoid was 11.7% of cases reported, diphtheria 9.3%, scarlet fever 3.6%, and measles 1.1%.

Transactions of the American Society of Tropical Medicine. Vol. 9. New Orleans, La. 1914.

This volume contains the papers read before the society at its Eleventh Annual Meeting held at Boston on May 29 and 30, 1914, together with papers published under its auspices. The volume opens with the address of its president, Dr. Richard P. Strong, in which he calls attention to the opportunities for investigators and for public health work in tropical diseases, the need for the endowment of a school for the training of physicians in this branch of medicine and the opportunity for trained physicians in Mexico and the American Colonial Medical Service. Dr. Aristides Agramonte of Havana, Cuba, writes on "The Late Outbreak of Plague in Havana," in which nineteen cases occurred with three deaths. Dr. Victor Heiser, Director of Health for the Philippine Islands, contributes a long article on the treatment of leprosy by the hypodermic use of chaulmoogra oil mixture, in which he states that use of this method has given more consistently favorable results than any other. It produces apparent cures in some cases, causes great improvement in many others and arrests the progress of the disease in almost every instance.

Dr. S. Burt Wolbach, of Harvard University Medical School, in an article on the filterability and biology of spirochaetes, states that the method of filtration as a means of separating spiral organisms from ordinary bacteria will probably hold good for other saprophytic and pathogenic spirochaetes and allied micro-organisms; that organisms larger than many bacteria will pass the Berkefeld V, N, and W filters, such as *Spirochaeta duttoni*, *Spirochaeta elusa*, *Spirochaeta biflexa*, intestinal spirochaetae; and that there is no evidence of spirochaetes multiplying by any other method than single fission. Dr. Edouardo Liceaga of Mexico City gives an account of the war waged against yellow fever and the mosquito in Mexico. The campaign began in 1903 and has continued without interruption at any season of the year. Its results have been, not only to do away with the serious yellow fever epidemics of former years, but to extinguish the endemic secular foci such as those hitherto existent at Vera Cruz and Merida. Dr. Richard P. Strong gives a brief account of his first expedition to South America in 1913, and his investigations of various tropical diseases, such as malaria, verruga peruviana, Oroya fever and uta.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, SEPTEMBER 30, 1915

EDITORS.

PREVALENCE OF SYPHILIS IN THE ARMY.

An attentive reading of the latest bulletin issued by the medical branch of our army justifies one in regarding apprehensively the ravages of syphilis. Dr. Vedder¹ has made an exhaustive study of this disease in the various branches of the service, including soldiers at the United States Soldiers' Home at Washington, D.C., the cadets at West Point, recently enlisted soldiers, and men who had just left the army. His diagnosis was made exclusively by means of the Wassermann reaction, which has been in use in the army since 1909. He states that a double plus Wassermann is considered to be a positive indication of syphilis, for in 1049 such cases where means of confirmation of the diagnosis existed there were found only four cases of error. A single plus Wassermann is considered as almost certain evidence of syphilis, as it was found to be 99% exact.

Captain Vedder reports the results of the examination of recently enlisted recruits who had passed the physical examination and were therefore presumably non-syphilitic. Among these men he found the double plus Wassermann in 7.75% and the single plus in 9.02%, that is, about one of them in six had syphilis. The vast majority of these men were between the ages of twenty-one and twenty-four. Vedder concludes from this that about 20% of all adult white males are syphilized.

We are inclined to think that this is too pessimistic, for it would seem that the career of an enlisted man in the army, as it is at present constituted, is not sufficiently alluring to attract a very high class of recruit. It is a well known fact among army medical officers that the present mental survey given recruits is not searching enough; and Captain Edgar King, of the United States Army Medical Corps, who has published his researches into mental disease and defect in the army as Bulletin No. 5 of the War Department, is at present endeavoring to get a measure passed which will provide for a more adequate mental examination of applicants for enlistment.

As a result of his examination of the cadets at West Point, Captain Vedder has come to the conclusion that 5.46% of them are syphilitic. This is rather appalling when we consider that if, about fifteen years from now, this country were involved in a war, some of these officers, by then advanced to the grade of colonel, or even higher, may be in the first stages of general paresis.

In his examinations of the enlisted men, Vedder found that among the white soldiers 16.08% have syphilis, and argues that, contrary to general belief, the morale of the enlisted man must be somewhat higher than of the man in civil life of about the same class. Prospective recruits are subjected to a very rigid physical examination, and those showing evidences of syphilis are rejected. This has the effect of making the soldier a picked man physically, while the rejected candidate remains in civil life and helps to swell the average of syphilitics there. Then, too, soldiers acquiring syphilis in such a form as to incapacitate them are discharged from the army, and their numbers add to the percentage of syphilis in civil life.

Among the negro soldiers, 35.30% were found to be syphilitic. This agrees with the observations of writers on syphilis in the negro, some of

¹The Prevalence of Syphilis in the Army, by Capt. Edward R. Vedder, U. S. A. Bulletin No. 8, War Dept.

whom state that approximately half of all adult negroes are syphilitic. All of them agree that syphilis is much more common among negroes than among white men.

Dr. Vedder has made a number of other studies which lack of space forces us to omit, but which are worth reading, such as studies of syphilis in the Porto Rican troops, the soldiers at the Government Hospital for the Insane, the members of the United States Soldiers' Home, and military convicts.

As might be expected, Captain Vedder has a number of conclusions to draw from his exhaustive studies. He believes that of the recruits who get into the army about 17% are syphilitic and a majority of these have never been diagnosed. Syphilis is much more frequent among the negro soldiers. The percentage is lower among army men than among men of a similar class in civil life. He expresses his belief that syphilis is a greater menace to public health than any other disease, not excluding even tuberculosis.

To check its ravages in the army Captain Vedder recommends the rejection of all syphilitic recruits, the presence of syphilis to be determined by the Wassermann reaction, or if this rejection is for any reason impracticable he thinks that only those syphilitics should be admitted who show no active signs of the disease, and that these should be given appropriate treatment during the whole of their stay in the army.

To decrease the infant death-rate remains at present our most effective method to offset the menace of a declining birth-rate.

In England, unfortunately, even this method seems, temporarily at least, to be yielding unsatisfactory results. The past year doubtless presents unusual circumstances, yet though the decline in the birth-rate might well be accelerated by war conditions, the infant death-rate in that country ought not to have increased as alarmingly as in point of fact it has done. Commenting editorially upon this situation, the issue of the *Lancet* for Sept. 4 says in part:—

"Recent statistical returns of the births and deaths of infants in this country are disquieting; regarded individually they are bad enough, but taken collectively they are distinctly alarming. The continued fall in the birth-rate, which has now reached the lowest level heretofore recorded, may have many explanations, but the factor of the deliberate limitation of families, whether from provident or selfish motives, can no longer be ignored. The dissemination of knowledge with respect to the use of contraceptives has undoubtedly contributed to this result, not only among the upper and middle classes, with whom their employment has been reduced almost to an exact science, but even among the poorest, with whom such practices were quite exceptional a decade ago. Whether this explanation has any bearing on the falsification of the prophecies of the scaremongers with respect to 'war babies' still remains to be seen, but from facts which are accessible to all those who keep their eyes open it is by no means improbable. While on these and other grounds the fall in the birth-rate is understandable, the figures published with respect to the mortality of infants under one year of age during the current year certainly demand more explaining than is afforded by the assumption that the position is due to a high prevalence of epidemic disease engendered by the unusual circumstances or to the dearth of doctors and nurses. That epidemic diseases have exacted a larger toll of infant life than usual cannot be gainsaid, but as an offset to this we must remember that the meteorological conditions have been distinctly favourable, while the many organizations which have been engaged in alleviating every form of distress have made it highly improbable that poverty has been concerned in the results. Indeed, it may almost be claimed that there has never been a time in the history of our country more free from want of employment, and the destitution which want of employment brings in its train, than the present moment.

"So serious does the position appear to those who are actively engaged in combating deaths among infants that the National Association for the Prevention of Infant Mortality has arranged for a conference at the Mansion House on Oct. 28, at which the Lord Mayor has consented to

THE MENACE OF A DECLINING BIRTH-RATE.

In the issue of the *JOURNAL* for Sept. 9 we commented editorially on certain aspects of the effect of education upon eugenics, particularly with reference to the decline of birth-rate, often observable among more highly educated types. From some points of view, perhaps, this phenomenon, much though it may be regretted, need not be regarded as a cause of alarm. In his leading article in this week's issue of the *JOURNAL*, Dr. Otis, discussing the conflict between nature and civilization, points out that the lamentable fact of the constant elimination of higher types must probably be accepted with resignation. Under existing conditions it cannot be prevented, and can best be combated only by attempts at eradication or improvement of inferior types.

preside, and at which the causes that are responsible for the present state of affairs will be fully discussed by many of the foremost authorities on the subject. It is to be hoped that out of the mouths of these many counsellors much wisdom will result, and that their advice, in addition to the benefits which are confidently expected from the operation of the new provisions of the Notification of Births Act, will help to relieve a situation which is beset with many national dangers."

The *Lancet* speaks with laudable optimism, yet probably little of permanent accomplishment may be expected of artificial regulations and measures, however wisely conceived. After all, the causes of declining fertility probably lie deep in race temperament and its reaction to changing environment. The will to survive and dominate is the first essential to doing so.

Precisely the lack or weakness of this will constitutes the real menace of the declining birth-rate which is its manifestation. The reasons for this "abnegation of the will to live" are not far to seek. They are pointed out by the two authors whose work on this subject we have already quoted.¹ The extent to which they have become operative throughout the world, especially in English-speaking communities, is undeniable. In New South Wales, for instance, the royal commission, appointed to investigate the declining birth-rate in that country, reported in part as follows, after a careful study of local birth statistics:—

"We are satisfied that the statistics show:

(a) That a decline of birth-rate in recent years has characterized all the states of Australia and New Zealand; also the United Kingdom; also many of the large cities of Europe, United States, and South America.

(b) That there was in New South Wales a sudden remarkable fall in birth-rate in the year 1899, followed by a continuance and rapid decline, until, in 1902, the total decline has exceeded 10 per 1000 population.

"There is no evidence of any increase of physiological sterility in women in New South Wales. . .

"The conclusions which we draw from the evidence on this branch of our subject are inevitable, namely, that there is a diminution in fecundity and fertility in recent years, which is due to:

(a) Deliberate prevention of conception and destruction of embryonic life.

(b) Pathological causes consequent upon the means used and the practices involved therein."

If these facts be true,—and experience and observation go far to show them so,—there would appear little prospect of abating materially the menace of a declining birth-rate merely by reducing infant mortality. To check the declining birth-rate induced in any nation by the circumstances of civilization, there must be a genuine regeneration of race instinct. The unconscious desire must be replaced by the conscious will to survive. Then, and then only, may there be expected a cessation of the constant destruction of higher types. Doubtless this adjustment of evolutionary economy will ultimately be made. Meantime it appears inevitable that families and races must continue to perish through lack of adequate will to persist.

A NEW THEORY OF THE NEUROTIC CONSTITUTION.

THE make-up of the neurotic has always been a fascinating subject. For many it has been a will-o'-the-wisp which has led them on to dangerous ground, where they with great difficulty held their balance, if they did not actually fall. The recent psycho-analytic movement led by Freud and propagated far and wide by his able followers, is a specific illustration of a definite effort to understand the neurotic individual.

Alfred Adler, of Vienna, a disciple of Freud, impelled by rather original concepts which found their birthplace in his mind, now offers a new theory of the make-up of the neurotic individual. This theory is sufficiently important to demand consideration by those who make it their business to understand their fellowmen.

In brief, Adler's concept of the character of the neurotic individual may be presented as follows: The neurotic is characterized by definite organic defect or inferiority. This somatic deficiency or inferiority, being concerned with one or more functions, and being unknown to the individual, is thus unconscious. The subnormal organs or functions are excessively unstable, irritable, sensitive, easily disturbed and unable to withstand or adapt to excessive or unusual stress. The other correlated functions attempt to compensate for the defective activity of the abnormal function or functions of one sort or another. But in the neurotic, complete and successful compensation fails to take place and there follow internal disharmony, unrest and instability of such a degree that the individual

¹ See JOURNAL, page 228.

² In last week's issue of the JOURNAL we pointed out editorially some of the evils of the artificial reduction of the birth-rate by methods of voluntary control.

finally becomes aware of his organic insufficiency and makes conscious efforts to compensate successfully. In efforts toward this end, the neurotic endeavors to hide his defects by various devices of concealment, and in so doing goes to extremes and overdoes himself, so that various peculiar traits and characteristics are developed, which constitute the peculiarities of the neurotic condition. Furthermore, in spite of these handicapping defects, the neurotic struggles to arrive at a state of equanimity and equilibrium, so that he will be like others. In this respect, too, he overdoes himself, and finds himself striving to outdo others, to excel them, to be all-powerful and superior, to attain self-maximation, or, in Adler's manner of expressing it, full masculinity.

The neurotic thus has a two-fold life's battle—to hide and make up for his organic defects and, despite them, to achieve full power and masculinity. It is but natural to expect that he will frequently have recourse to unusual, immature, even child-like methods of reaction. In certain cases and under certain situations compensation is impossible and then we find varying degrees of decompensation developing, from simple anxiety to the many psychoneurotic and psychotic disorders. But even in decompensation there is for the individual a salutary recourse, for in this world of unreality which he builds up for himself he can at least continue to survive without immediate and complete disintegration of the personality.

It now remains to prove or disprove the truth of these ideas. Even though this concept may not apply *in toto* to the neurotic, the general idea may at least be found useful in the elucidation and understanding of many apparently peculiar mental states, normal or abnormal.

MEDICAL NOTES.

NEW YORK DEATH RATE.—Despite the fact that during the week ended Sept. 18 New York experienced the warmest and most humid weather that has visited the city during September in more than a score of years, the death rate was .83 per 1000 population lower than during the corresponding week of last year. Especially noteworthy is the fact that the deaths from diarrheal diseases under five years were fewer than during the week ending September 19, 1914.

The following causes of deaths showed a decrease: Scarlet fever, diphtheria and croup, pul-

monary tuberculosis, Bright's disease and nephritis.

During the week there were four deaths from sunstroke, as compared with 1 death from the same cause during the corresponding week of last year.

The deaths during the week numbered 1291 with a rate of 11.60, as compared with 1330 deaths and a rate of 12.43 for the week ending September 19, 1914. The difference of .83 in the weekly rate means a saving of 92 lives. The death rate for the first 38 weeks of 1915 is 13.49, as compared with 13.94 for the first 38 weeks of 1914.

INCREASE OF ANTI-TYPHOID VACCINATION.—The United States Public Health Service reports that the use of typhoid antitoxin is rapidly becoming general. It is estimated that during 1914 over 100,000 persons throughout the country were immunized, and it is believed that in 1915 the number will exceed 300,000. In four counties of North Carolina, where campaigning has been conducted, it is estimated that 20,000 people will be immunized.

INHERITANCE OF TEMPERAMENT.—In the August issue of the *Proceedings* of the National Academy of Sciences is an article on "Inheritance of Temperament" by Dr. C. B. Davenport, of the station for experimental evolution, Carnegie Institution, Washington, D.C. This paper, which is based on a careful statistic study of 89 family histories, suggests that the various types of human temperament are dependent on definite, heritable physical factors.

"Temperament is hereditary and as little alterable as stature. There are involved in the inheritance of temperament two factors,—one which induces more or less periodic excitability and whose absence results in calmness, another which makes for normal cheerfulness and whose absence permits more or less periodic depression—these factors being inherited independently and occurring in any combination. Persons may be divided into calm, nervous, or choleric according to their degree of excitability, and into cheerful, phlegmatic and melancholy, according to their degree of cheerfulness or its opposite. There are, therefore, nine classes of temperament formed by combining these two classes, namely, choleric-cheerful, choleric-phlegmatic, choleric-melancholic, nervous-cheerful, nervous-phlegmatic, and so on.

"The statistical study of the 89 carefully described family histories seems to bear out this hypothesis, because the different classes of temperament actually occur with about the relative frequency which would be expected from the hypothesis and the usual laws of inheritance."

DECLINE OF SWEDISH BIRTH RATE.—The census of Sweden, which has recently been com-

pleted, shows the present population of that country to be 5,679,607. It also shows a steady decrease of marriages and births, so that during the past year the birth rate has been lower than at any time since vital statistics have been kept in Sweden.

LONDON DEATH RATES IN JULY.—Statistics recently published show that the total death rate of London for July, 1915, was only 11.1 per 1000 living inhabitants. Among the several districts and boroughs the highest rate was 16.7 in the old city precincts, and the lowest was 6.7 in Hampstead on the north.

ENDOWMENT OF DUNN LECTURESHIP.—It is announced that the trustees of the estate of the late Sir William Dunn have given to Guy's Hospital the sum of £25,000 sterling, for the endowment at Guy's Hospital Medical School of the Sir William Dunn lectureship in pathology.

THE TALL OR THE SHORT SOLDIER.—At a meeting of the Royal Sanitary Institute in London the question of whether the tall man or the short man made the better soldier was discussed at some length. Dr. Pembrey of Guy's Hospital stated that: "In times of peace height is a recognized standard for recruits, and most men will agree that the tall soldier is more imposing, docile and dignified than the short one." He, however, goes on to state that measurements may not be an accurate estimate of the value of a soldier who has, first of all, to bear the physical and mental strain of the campaign, to march, to shoot straight and to subordinate his personal interests to those of his race and country.

"Some of the advantages of the short man are his relatively greater agility and activity and relatively greater surface, which in hot weather and doing muscular work is a decided advantage. There are mechanical advantages and disadvantages in height. A consideration of these in relation to the work of the soldier results generally in favor of the little man."

Average heights of the men of the divisions of the British Isles have been computed as follows: for Scotsmen, 68.71 inches; for Irish, 67.90; for English, 67.36; and for Welsh, 66.66, the average for the kingdom being 67.66 inches, with a weight of about 170 pounds.

MORTALITY AMONG SAILORS.—It has been computed, from a classification of 8000 deaths in two years in the English merchant service, that accident and consumption cause the greatest number of deaths of sailors. Nervous diseases come next with pneumonia and bronchitis, and heart disease and Bright's disease rate fairly low. Alcoholism is responsible for only one per cent. of the deaths. The mortality rates are everywhere much higher than for the population on shore.

EUROPEAN WAR NOTES.

MAINTENANCE OF HOSPITALS IN PAIGNTON AND PETROGRAD.—It is announced that in spite of the withdrawal of American Red Cross Hospital units from Europe on October 1, the American Women's Hospital at Paignton, Devonshire, will continue to be maintained during the winter by private support. It is similarly announced that the American colony at Petrograd not only has voted to continue the maintenance of the American Hospital in that city, but has raised funds to pay for its enlargement from its present capacity of 28 beds to a capacity of 40.

APPOINTMENT OF DR. BLAKE.—Report from Paris announces that on Sept. 18 Dr. Joseph A. Blake resigned from the American Ambulance Hospital at Neuilly to accept an appointment as surgeon-in-chief of a new general hospital at Risorangis, near Fontainebleau, which will take care of the British wounded at Versailles. This hospital is to have twice the capacity of the American Ambulance.

OPENING OF LANGENBECK-VIRCHOW HAUS.—It is announced that the new Langenbeck-Virchow Haus, to be occupied by the Berlin Medical Society and the German Surgical Association, was opened on August 1. The formal dedication will take place at the close of the war.

NEEDS OF AMERICAN RED CROSS.—At the close of its first year of work among the belligerent countries of Europe, complicated as it has been by urgent calls for assistance from other parts of the world, the American Red Cross finds itself in acute need of funds for the continuation of its activities during the coming winter. The following letter from Miss Mabel T. Boardman at Washington to Miss Louisa P. Loring, emergency secretary of the Red Cross for Massachusetts, explains some of the plans of the organization for the coming season. It is earnestly to be hoped that there will be an ample public response to the call for funds from an organization whose activities have reflected such great credit upon the United States in the past and especially during the present war:

"Dear Miss Loring;—Your second letter of the sixteenth is just received. I think the suggestion you make of replenishing our contingent fund a most excellent one. We so often have sudden calls upon it, and it is becoming very much exhausted. For example, Admiral Caperton telegraphed to the Navy Department the other day begging the Red Cross to send him \$1000 for the destitute in Hayti. One woman and one child had already been found dead from starvation in the market place. We were able to send the \$1000, greatly to the gratification of

the navy and of the poor people who are suffering there. The money we sent to the Samoan Islands last winter, though only \$2000, has been a great help to the poor there. Not long ago it was \$500 worth of food supplies sent from Manila to save the lives of some hundreds of people in the Ladrone Islands that the governor of Guam reported to be starving. This will tide them over until Japan, which has taken the islands, can look out for them, and we have written the Japanese Red Cross asking it to take over the relief of these Ladrone Islands.

"The Mexican situation continues as you know, very complicated: but Mr. O'Connor, our agent, is, according to official reports, doing very fine work in Mexico City, and Mr. Weller, another agent of ours, has just obtained consent from the governor of Saltillo to take any food there under guard, and we are sending eight more carloads to Monclova and Saltillo. Mr. Weller reports that when he got to Saltillo the doctors told him the day before seven persons had died, and, the autopsy showed, from absolute starvation, and that the bodies contained no food. The public officials made them put it down as death from stomach trouble, which seemed ironical, as there was nothing to trouble their poor starving stomachs. Mr. Bonsal, whom we sent there is just back and he says the suffering which is increasing all the time, is beyond words. All our funds for Mexico have been used up, as we have had to send our last \$6000 to Mr. O'Connor in Mexico City, but we do not want to put out a general appeal until the Government's policies are more definitely settled, both here and in Mexico.

"I am going to see that the last contributions given you (\$300 and \$500), which you say are undesignated funds (these two donors especially desired that their gifts should go to any department preferred), are put in the Mexican fund, as I believe nowhere is there really more acute suffering than there, and there really is nobody but the United States who can or will help them.

"Yours sincerely,

"Mabel T. Boardman."

Therefore, the undesignated fund in Massachusetts will now be collected for the American Red Cross to be expended in any way that is deemed most expedient at headquarters, unless the donors state that their gifts shall go to the war relief department, which also continues as in the past year.

All donations will be gratefully received by F. L. Higginson, Jr., treasurer, Massachusetts Red Cross, 44 State street, Boston.

SHORTAGE OF PHYSICIANS IN ENGLAND.—In the issue of the JOURNAL for July 22, we noted the increasing shortage of medical men in Great Britain, especially in the rural districts where the condition has become really serious. The issue of the *Lancet* for August 28, is students'

number. There is a special editorial discussion of the situation as follows:—

"That our medical schools will go very short of students is certain, and this will mean a dangerously small list of medical practitioners to minister to the needs of the country in the near future. The position is inevitable. The spirit which will lead young men of the military age and the educated class to join the army must have this effect, but it is the duty of the medical profession to face the difficulty and to make the best of it.

"The great work which the medical contingent with the army and navy has accomplished in the present war will act later as a stimulus to enthusiasm for our calling, and the shortage which must occur in our ranks for the three or four years following—say, 1917—will speedily remedy itself, when our social world resumes, as far as altered circumstances will permit, the scheme which we had, with considerable lack of prevision, come to regard as the normal one.

"The war found the number of the medical profession in this country already disquietingly low, and with indications of further sagging in those numbers. The figures indicate a serious shortage of medical men for the years following the war. Not only has a large number of young men who otherwise would be beginning or pursuing their medical studies been absorbed, but, unfortunately, a serious toll was already taken last autumn of those who, being already nearly qualified, would have been able to practice their professions as qualified men in a few months.

"The future will see an increased demand for medical men, and their prospects of success will be so great that the aspirants will assuredly be numerous. And there will be an improvement in the conditions which have prevailed in the past, not only because the profession of medicine will share in sociological progress, but because the record of the work of medicine throughout the war has been such that it must lead to a closer relationship between the medical profession and the public.

"The British public are taking a more intelligent interest in these things, and the energy with which lay bodies are working in coöperation with the medical profession in carrying out various schemes for the well-being of the people may be taken as an indication that the health of the nation will be a first consideration of the immediate future—which means that there will be a great demand for medical men at the close of the war.

"And this is the essential message to the students now in the schools. They are already wanted as qualified men, and in the near future they will be wanted even more urgently. It is a patriotic duty, imposed upon them by the conditions of the world, that they should spare no effort to pass all their tests in the shortest legal time, while by doing so they will reap the double reward of good citizenship and worldly success."

WAR RELIEF FUNDS.—On Sept. 25 the totals of the principal New England relief funds for the European war reached the following amounts:

Belgian Fund	\$272,319.67
Polish Fund	50,630.04
British Fund	33,422.39
Italian Fund	3,418.10

BOSTON AND NEW ENGLAND.

WELFARE OF BABIES IN HOT WEATHER.—The extreme heat of week before last added greatly to the work of the Milk and Baby Hygiene Association at its twelve stations throughout the city. During four of the hottest days 1854 children were looked after, and the mothers instructed in various practical ways of keeping the babies cool. The greatest need now confronting the Association is money for a second nurse for its milk station in the North End Union, where there is a registration of 229 babies. Unless more funds can be raised the special summer nurse will have to leave on September 30. The work of the organization, requiring a budget of \$24,000, is carried on entirely by voluntary subscriptions.

HOSPITAL BEQUESTS.—The will of the late Charles E. Davis, of North Andover, Mass., which was filed in the Essex Probate Court of Salem, Mass., on Sept. 21, contains a bequest of \$5000 to the Salem Hospital for a child's freed bed. The Salem Hospital and the Massachusetts General Hospital are among the four residuary legatees.

The will of the late Maria J. Shepherd, of Revere, Mass., which was recently filed for probate in the Suffolk registry, contains bequests of \$1500 to the Lynn (Mass.) Hospital, and \$400 each to the Boston Floating Hospital and the New England Peabody Home for Crippled Children.

The will of the late Mary Ann Smith, of Chelsea, Mass., who died on Sept. 9, was filed on Sept. 19, in the Suffolk probate court. It contains bequests of \$500 each to the Rufus S. Frost General Hospital, Chelsea, and the New England Deaconess Hospital, Longwood. Both these institutions are also named as residuary legatees.

QUINCY HOSPITAL TRAINING SCHOOL.—The annual graduation exercises of the Quincy (Mass.) Hospital Training School for Nurses were held in that city on September 2. The principal addresses to the graduates were made by Dr. George W. Gay of Boston and by Dr. John A. Gordon of Quincy. Diplomas were awarded to four pupil candidates.

MEETING OF SOCIAL HYGIENE ORGANIZATIONS.—On Friday of next week, Oct. 8, will be held at the Copley-Plaza Hotel, Boston, the annual

meeting of the American Social Hygiene Association in conjunction with the Massachusetts Society for Social Hygiene. The former organization was established in 1913 by the amalgamation of the American Federation for Sex Hygiene and the American Vigilance Association. The state society is an outgrowth of the former Massachusetts Society for Sex Education.

"The joint session will be held at the Copley-Plaza on Oct. 8. The morning session will be devoted to routine business, followed by luncheon; but at the afternoon and evening sessions, to which the public is invited, addresses on timely subjects will be treated from the moral and scientific point of view. Among those on the program at the afternoon session are Dr. John D. Trawick of Louisville and Dr. Rollin H. Stevens of Detroit, both of whom are city health officers; Dr. Thomas W. Salmon of New York City, secretary of the National Commission on Mental Hygiene; Dr. George A. Coler of Rochester, N. Y.; Dr. Allan J. McLaughlin of the Massachusetts State Board of Health; Samuel H. Adams of New York, one of those who carried on the American Medical Association propaganda against impure drugs and foods; Dr. S. S. Goldwater, health commissioner of New York; Dr. C. E. Banks of Washington, D. C., a Federal health officer; Dr. Edward L. Keyes, Jr., of New York; Dr. F. N. Whittier of Brunswick, Me.; and Dr. C. F. Dalton of Montpelier, Vt."

Dr. David L. Edsall of Boston will preside at the evening session.

Obituary.

SIR PETER EADE, M.D., LOND., F.R.C.P., LOND.

DR. SIR PETER EADE who died in Norwich, England, on August 12, was born at Acle, Norfolk, in 1825, the son of a local surgeon. He began the study of medicine as apprentice to his father, then in practice at Blofield and continued it under the eminent surgeon, Mr. John Greene Cross, F.R.S., at the Norfolk and Norwich Hospital. At the conclusion of his apprenticeship he entered Kings College, London, where he had a brilliant career as a medical student and graduated in 1847 with a gold medal and several prizes. He received the degree of M.D., in 1850.

Though offered an assistant surgery in the Indian Medical Service, Dr. Eade preferred to settle in practice with his father. In 1856 he removed to Norwich where he was appointed to the Norfolk and Norwich Hospital in 1858. Here his service was that of both a physician and a surgeon, and in 1873 he was elected a fellow of the Royal College of Physicians. He was also consulting physician to the Norwich Public Dispensary, the Jenny Lind Infirmary for Sick

Children and the Children's Convalescent Home at Yarmouth. Upon his retirement in 1888 he was appointed consulting physician to the Norfolk and Norwich Hospital.

Dr. Eade was noted throughout his county and indeed through the whole of East Anglia as a consultant. He was the author of a history of the Norwich Hospital and of monographs on influenza, diphtheria, furunculosis, diabetes insipidus and the local use of cold in abdominal inflammation. In 1874 when the British Medical Association met at Norwich he was president of the section of medicine. Dr. Eade also devoted himself extensively to local improvements and municipal politics and was thrice mayor of his city. For his public services he received the honor of knighthood in 1875. His long and active life was typical of that of the best of the older time British provincial practitioners.

Two of his colleagues writing of him in the issue of the *British Medical Journal* for August 21, speak as follows of his personality:

"The death of Sir Peter Eade has robbed the profession of one of the most eminent physicians in the Eastern Counties, and the city of Norwich has lost a very distinguished citizen. He has left us at the mature age of 90 years with all his faculties unimpaired, and able to take a keen interest in the affairs of life to within a few days of his decease.

"Having been intimately connected with him for more than fifty years professionally and otherwise, I could but admire the energy he displayed in all he undertook and his patient attention to the smallest details. As a physician he was well known as a consultant of the best type, and when gradually withdrawing from his professional duties at the age when most are glad to retire altogether, he kept up his reading and took the greatest interest in all modern modes of treatment and ever interested himself in the welfare of the Norfolk and Norwich Hospital, with which he had been so long and honorably connected, and also in all the philanthropic movements in the city and the parish in which he lived.

"Of small stature and frail physique he was ever quick and active in his movements, with which the activity of his mind seemed to correspond. Although holding strong opinions on many subjects, he was most tolerant of those who differed from him, and generous and honorable in all his actions, with an extremely kindly disposition. He lived his long life amongst us gaining not only the esteem and admiration of all, but the affectionate regard of those who best knew him and with whom he was almost in daily contact.

"Sir Peter was vigorous in argument, taking a very strong line on his personal conviction, but he never was known to bear the slightest malice to his opponents five minutes after the most heated controversy. He was a staunch friend to many but an enemy to none. Honorable to

a degree in all transactions, he would go out of his way to do a kind action for anybody requiring it. This I can testify to from personal experience. His purse was ever open to the poor of his parish, and they made free use of it. As a host he could not be excelled; his luncheons to the profession of the city and county, and his society dinners of twenty years ago were widely known and much appreciated. Sir Peter was genuinely loyal to all his colleagues, even at times under trying circumstances, and I cannot recall having ever heard his make an unkind remark about a member of the profession."

Miscellany.

MEDICAL CONDITIONS IN CHINA.

DURING the current year the JOURNAL has had occasion several times to present material regarding various aspects of medical conditions in China. In the issue of the JOURNAL for January 14 we commented editorially on Dr. Peabody's work with the Rockefeller Commission in making a medical survey of China, and on an article by Dr. William W. Cadbury of Canton in the *China Medical Journal* on medicine as practiced by the Chinese. In the issue of March 11 we presented a further editorial on the organization of the Human-Yale Medical School in China and on the new era which has recently developed in Chinese medical education. In the issue of March 25 we further quoted from a letter by Dr. Edward H. Hume descriptive of this school, and discussing particularly the work of the China medical commission of the Rockefeller Foundation. In the issue of the JOURNAL for June 17 appeared an article by Dr. Reed on the prevalence of rabies in China. Compared with the stagnation of preceding centuries it appears that there has been a definite awakening of medical activities in China within recent years. The *British Medical Journal*, in its issue for June 19, presents the following editorial comment on the report of the China Medical Commission, a summary of which was published in the *Johns Hopkins Bulletin* for June.

"The commission, which was composed of President Judson of the University of Chicago, Mr. Roger S. Greene (American Consul at Hankow), and Dr. Francis W. Peabody of Boston, with Mr. George B. McKibbin as secretary, visited seventeen medical schools and ninety-seven hospitals in China and Manila. The commissioners state that the death-rate in China is probably higher than in any other country. The most widespread and destructive diseases are tuberculosis, hookworm disease, and syphilis. Leprosy is also common, and smallpox is looked upon as an inevitable incident of human life. There is no legal restriction on medical practice. The native materia medica mainly consists of

herbs, but modern 'patent' medicines command a large sale. The Chinese doctors know nothing of surgery; this is due to their ignorance of anatomy. Dissections and post-mortem examinations were not officially authorized till November 22nd, 1913. There are some Chinese physicians trained in Western medicine, but they practise mostly in the treaty ports or are attached to mission hospitals. The medical schools are classed in four categories: (1) Government and private schools; (2) missionary schools; (3) schools for Chinese women, and (4) non-missionary schools under foreign control. The strictly Chinese schools suffer from great disadvantages caused by disturbances of the political atmosphere during the last four years and the financial difficulties of the Government. Not one of them is properly equipped or adequately staffed, and not one has access to a satisfactory hospital. China has three hospitals for women alone, besides two in which they may be educated with men. But these schools are small and poorly equipped, and there is a difficulty in getting students who have had a proper preliminary training. The non-missionary schools under foreign control are five in number: Japanese in Mukden, German in Tsingtau (of this we suppose we may now say *fuit Ilum*) and Shanghai, French in Canton, and English in Hong Kong. The commission found that a study of hospitals in China 'resolves itself almost completely into a consideration of the mission hospital. The more important non-missionary hospitals established by foreigners are for the care of foreigners, and have no very definite influence on China itself. The hospitals under Chinese control, whether Government or private, are, with few exceptions, ineffective, and they are chiefly of interest as demonstrating how small an impression high-grade Western medicine has as yet made on China.' Among the recommendations of the commission are the following: 'That the Foundation should undertake medical work in China, and as far as possible should cooperate with existing missionary institutions.' 'That it is not advisable at this time to establish an independent institution for research, but that research be encouraged in connexion with the medical schools aided by the Foundation.' 'That the first medical educational work be in Peking in connexion with the Union Medical College, that a new school be established in Shanghai, and provisions be made for cooperating with existing schools in and near Shanghai in order to unify medical effort in the lower Yangtse Valley; and that assistance be given the Canton Christian College, and that the Yale Mission at Changsha be aided in its medical plans.' 'That two model tuberculosis hospitals be established.' The other recommendations refer to the foundation of fellowships and scholarships for Chinese students, the training of nurses, and the establishment of central diagnostic laboratories in Peking and Shanghai. They sketch out a broad scheme of medical education which has for its

ultimate object a national system of public health administration. The commissioners insist that, if the scheme is to be successful, it is essential that a large number of natives of China should be thoroughly trained in the methods of Western medicine.'

Correspondence.

MASSACHUSETTS DAIRY INDUSTRY.

CITY HALL, WEST NEWTON, Sept. 15, 1915.

Mr. Editor: Although much has been said and written about the decay of the Massachusetts dairy industry, the question is one of such vital importance that I am tempted to make a few observations based upon a recent inspection of a number of Massachusetts dairies. During the trip some 250 dairies situated in the northwestern and central part of the state and in the metropolitan district, all sending milk to the cities and towns in the district, were inspected.

I will not take the time to analyze the scores further than to say they ranged from 23 to 99 and that the further they are situated from the point of delivery the lower the score. Incidentally this holds good for other parts of New England, the out-of-state dairies averaging lower than those in Massachusetts.

I was impressed by the fact that there is no inducement for the farmer to produce high grade milk, for the man whose dairy scores over 80 receives the same price as the one who scores below 30, and the man whose milk has a high fat content is paid no more than one whose product just passes the standard.

Under Chap. 744 of the Acts of 1914 no dairy can send milk into any city or town in Massachusetts until it has been approved by the Board of Health of that city or town. This means that a dairy selling milk to a large contractor, who mixes his milk, must be inspected by every city and town in which that contractor delivers milk and must conform to the requirements of each; too often these requirements are very diverse and what will pass in Newton may fail to pass in Brookline, and both may be unacceptable to Boston. In any event the farmer must do certain things in order to have his product pass, and so his cost of production is increased.

On the other hand he is at the mercy of the large contractor for his market and as the price paid is practically based upon milk of the lowest grade, he must accept what is offered or lose his market.

At the time the inspection was made the contractor's price was \$1.60 per 100 pounds but as there are certain deductions for cartage, etc., the net price averaged about \$1.50 per 100 pounds or .63¢ per quart. I am sure that there are premiums offered but as there seemed to be no check governing the payment of these premiums the result is that anyone whose conscience is a trifle dull can obtain the premium.

One practical result of all this is that the dairymen are made up chiefly of cows which will give a large amount of low grade milk and that many men who had Jerseys and Guernseys stated that they were going to dispose of them and replace them with other breeds giving milk with a smaller fat content.

Milk production is one of the few forms of business where a high grade product does not command a higher price than a poor one and it must be so for its very nature. The farmer must market his product at once for what he can get or lose it entirely and consequently must take what he is offered no matter what it is a loss. One man, in reply to a remark about the small number of cows in his herd, said, "Well, if I had more cows I'd lose more money."

There must be a remedy for such a condition and I believe it to be a very simple one. The farm-

should receive a better price for a better product but to do this the public must be willing to pay more for its milk. Let the milk be graded so that the consumer by paying a cent more per quart can have better milk.

It has been proved again and again that premiums to the producer, varying from one-eighth to one-fourth cent per quart for certain standards almost immediately produce those standards. Low bacterial count and high fat content should bring a higher price to the producer. We ask the farmer to do these things now, thus increasing his cost of production, but we refuse to pay him for doing them and naturally he objects.

Contrary to the usual belief it is not necessary to have a modern concrete barn to produce clean milk; such an equipment is to be desired but it does not necessarily produce clean milk. Methods count more than equipment and a careful man can produce milk in an old barn, with lower bacterial count than a careless man can produce in a concrete barn.

Let us bend our energies to obtaining a better price for the farmer for clean milk so that there will be an inducement for him to produce it and the result will be an almost immediate increase in the quality of our dairy milk and a gradual revival of the dairy industry in Massachusetts. This will give us a fresher and better supply for domestic use, as it will shut out the low grade milk from distant points; but we must be willing to pay for it.

As long as we object to paying a fair price for a good product so long shall we have low grade milk, brought from a distance, crowding Massachusetts milk from our markets.

FRANCIS GEO. CURTIS, M.D.,
Chairman, Newton Board of Health.

AN HISTORIC MEDICAL LANDMARK.

CAMBRIDGE, MASS., Sept. 16, 1915.

Mr. Editor: I have recently learned that there are plans on foot to demolish the house at Wellesley formerly occupied by Dr. Morton, who first publicly demonstrated the anesthetic effects of ether. The tract of land upon which the Morton house stands has been purchased from the Hunnewell family by Mr. Roger W. Babson of Wellesley Hills who is about to erect an apartment house there. To make way for the new building the Morton house must be torn down. It seems to me that this valuable historic landmark should be preserved. May I suggest that in view of the fact that the epoch-making demonstration of ether anesthesia took place at the Massachusetts General Hospital it would be peculiarly fitting that the Massachusetts Medical Society should take immediate steps to preserve Dr. Morton's house at Wellesley and place a suitable tablet upon it to commemorate its illustrious occupant?

I have talked with Mr. Babson and find that he is willing to delay the destruction of the building pending any action which the Society may see fit to take.

Very truly yours,

W. STEWART WHITTEMORE, M.D.

AN EARLY MODERN REFERENCE TO THE WORK CURE.

PROUTS NECK, ME., Sept. 17, 1915.

Mr. Editor: In Tolstoy's "Anna Karenina," which was first published in 1875, occurs the following: It is supposed that Levin, the speaker, was a faithful picture of the great author himself, as was David Copperfield, of Dickens.

Levin had been passing a strenuous day with his *hazika*, mowing, much to his brother's amusement. "The sight of his brother irresistibly filled him with

happiness. 'Nu! what an appetite you have!' he added, as he saw his tanned, sunburned, glowing face and neck, as he bent over his plow.

"Excellent. You can't imagine how this sort of thing drives all foolish thoughts out of one's head. I am going to enrich medicine with a new term, *arbeitskur* (labor cure)."

"Nu, you don't seem to need it much, it seems to me."

"Yes it is a sovereign specific against nervous troubles."

Very truly yours,

WM. PEARCE COLES, M.D.

DIAPHRAGMATIC PARALYSIS IN POLIOMYELITIS.

NEW YORK, Sept. 17, 1915.

Mr. Editor: In your issue of Sept. 16, 1915, an especially interesting article on poliomyelitis by Dr. Sylvester, states, in its chief title, "A Hitherto Unrecorded Involvement of the Left Diaphragm."

Dr. Sylvester has overlooked the literature of poliomyelitis, else he would have found this paralysis recorded. In Jelliffe and White's just issued Diseases of the Nervous System, p. 312, the facts of complete and unilateral involvement of the diaphragm are specifically stated and the literature there cited also speaks of these facts. I think your readers would care to have this correction, inasmuch as Dr. Sylvester makes specific claim to priority in discovery. I am unable offhand to tell who first described it, but I suspect, either Heine or Medin.

Very respectfully,

SMITH ELY JELLIFFE, M.D.

BELGIAN PHYSICIAN'S RELIEF FUND.

REPORT OF THE TREASURER OF THE COMMITTEE OF AMERICAN PHYSICIANS FOR THE AID OF THE BELGIAN PROFESSION FOR THE WEEK ENDING SEPT. 18, 1915.

Total receipts.....	\$7814.84
Total disbursements.....	\$7310.04
Balance	\$ 504.80

Pittsburg, Pa.

NOTICES.

EXAMINATION OF CANDIDATES FOR ASSISTANT SURGEON.

UNITED STATES PUBLIC HEALTH SERVICE.

Boards will be convened at the Bureau of Public Health Service, 3 B Street, S.E., Washington, D. C., and at the Marine Hospitals of Boston, Mass.; New York, N. Y.; Chicago, Ill.; St. Louis, Mo.; Louisville, Ky.; New Orleans, La., and San Francisco, Cal., on Monday, Nov. 1, 1915, at 10 o'clock A.M., for the purpose of examining candidates for admission to the grade of Assistant Surgeon in the Public Health Service.

Candidates must be between 23 and 32 years of age, graduates of a reputable medical college, and must furnish testimonials from two responsible persons as to their professional and moral character. Credit will be given in the examination for service in hospitals for the insane or experience in the detection of mental diseases. Candidates must have had one year's hospital experience or two years' professional work.

Candidates are required to certify that they believe

themselves free from any ailment which would disqualify them for service in any climate. Examinations are chiefly in writing, and begin with a short autobiography of the candidate. The remainder of the written exercise covers the various branches of medicine, surgery, and hygiene.

Successful candidates will be numbered according to their attainments on examination, and will be commissioned in the same order. They will receive early appointments. After four years' service, assistant surgeons are entitled to examination for promotion to the grade of passed assistant surgeon. Passed assistant surgeons after twelve years' service are entitled to examination for promotion to the grade of surgeon.

Assistant surgeons receive \$2000, passed assistant surgeons \$2400, surgeons \$3000, senior surgeons \$3500, and assistant surgeon-generals \$4000 a year. When quarters are not provided, commutation at the rate of \$30, \$40, and \$50 a month, according to the grade, is allowed. All grades receive longevity pay, 10 per cent. in addition to the regular salary for every five years up to 40 per cent. after twenty years' service. The tenure of office is permanent. Officers traveling under orders are allowed actual expenses.

For invitation to appear before the board of examiners, address

SURGEON-GENERAL, PUBLIC HEALTH SERVICE,
Washington, D. C.

COURSE FOR DENTAL NURSES.

The Forsyth Dental Infirmary for Children, Boston, is about to establish a course for Dental Nurses. The Massachusetts Dental Registration Law of 1915 permits the employment of dental hygienists in public institutions.

Candidates for entrance to the course must be 18 years of age, of good moral character, and must present certificates of graduation from high schools recognized by the College Entrance Examination Board or the equivalent of a four-years' high school course.

The course of study will be one year of twelve months. The instruction will be given in the Forsyth Dental Infirmary for Children. The fee will be \$50.00.

An advanced course for Registered Medical Nurses will be offered. The course which will extend through a period of four months will deal with training in fundamental dental branches including practical technique. The fee will be \$25.00.

For information apply to

HAROLD DEW, CROSS, D.M.D.,
No. 140 The Fenway, Boston, Mass.

APPOINTMENTS.

BOSTON HEALTH DEPARTMENT.—The following have been appointed to positions in the child hygiene division of Boston: *Dr. John S. Brounrigg*, *Dr. William J. McNally*, *Dr. Gactano Praino*, *Dr. Henry F. R. Watts*, and *Dr. Charles F. Willinksky*.

CALIFORNIA STATE BOARD OF HEALTH.—*Dr. Wilbur F. Saurper*, director of the California Hygiene Laboratory and lecturer on hygiene and preventive medicine at the University of California, has been appointed a member and secretary of the State Board of Health.

RECENT DEATHS.

DR. JOHN MERRICK BEMIS, a Fellow of The Massachusetts Medical Society, died at his home in Worcester, Mass., September 22, aged 55 years. He was a graduate of the University of Vermont College of Medicine and succeeded his father in the superintendency of the Herbert Hall Hospital in 1904.

DR. AMELIA BURROUGHS, who died at Boston on Sept. 25, was born in Omaha, Neb. She received the degree of M.D. in 1881 from the Homeopathic Hospital College, Cleveland. She was a member of the American Institute of Homeopathy and of the Massachusetts Homeopathic Medical Society.

DR. DEBORAH SMITH DEURY, who died on August 22, at Haverhill, Mass., was born at Andover in 1824. She received the degree of M.D. from the Women's Medical College of Pennsylvania, and during the Civil War practised her profession at Fall River, Mass. She subsequently removed to Boston and then to Haverhill. She is survived by one son.

DR. CHARLES EUGENE ESTABROOK, of Boston, who died recently of tuberculosis at Jacksonville, Fla., was a native of England. Coming to the United States in 1879, he graduated from the Harvard Dental School in 1883 and then studied medicine for three years. In 1887 he settled in the practice of dentistry in South Boston, but retired some years ago on account of ill health.

DR. DAVID HUNT, of Worcester, Mass., died of cerebral hemorrhage on September 15 in Detroit, Mich. He had been a practitioner in Boston and Worcester, making a specialty of ophthalmology and otology. He is survived by his widow and three daughters.

DR. JEAN PHILIPPE ALPHONSE GARNEAU, who died on September 21 at Fall River, Mass., was born at Quebec in 1868. He studied medicine at Laval University, and since 1895 has practised his profession in Fall River. He was a member of the Fall River Medical Society. He is survived by his widow and three sons.

DR. ANDREW V. JOVA, who died recently at Newburgh, N. Y., was born in Cuba in 1859. He received his medical education at the College of Physicians and Surgeons in New York and had practised his profession at that city and Newburgh.

DR. WILLIAM F. MÜHLENBERG, who died on August 25, at Reading, Pa., was born in Gettysburg in 1853. He was for many years one of the leading general practitioners of eastern Pennsylvania.

DR. CHARLES E. NICHOLS, who died recently in Boston, was a native of this city. He received the degree of M.D. from the University of Vermont in 1868.

DR. JUSTIN N. ROGERS, of Patten, Me., who died on September 16, at Farmington, Me., was born in Monson in that state, in 1880. He had practised at Patten for several years. He is survived by his widow.

DR. ERASMUS D. SKINNER, who died at Minneola, Long Island, on September 20, was born at Greenport, L. I., in 1843, the son of a physician. He received the degree of M.D. in 1875 from the Berkshire Medical School. He is survived by his widow, one daughter, and two sons.

DR. HENRY STEARNS, of Concord, N. H., was killed in an automobile accident in Haverhill, N. H., on August 23. He was 45 years of age and had been a practitioner in Concord for nearly 15 years.

DR. JOHN E. SUEPPARD of Brooklyn, N. Y., who died of carcinoma on Sept. 13 at Putnam, Conn., was born in 1839. In his practice he had made a specialty in diseases of the eye, ear and nose. He was a member of the American Medical Association and of the Academy of Medicine. He is survived by his widow and by one child.

OUR CRIMINAL PROBLEM FROM THE STANDPOINT OF CLASSIFICATION AND SEGREGATION.*

By EDITH R. SPAULDING, M.D., FRAMINGHAM, MASS.,

*Resident Physician, Reformatory for Women,
Framingham, Mass.*

It is our belief that the at present much agitated problem of prison reform has become more and more one for the medical profession to help in solving. Diagnosis of the individual delinquent is essential as a foundation for reform, and that diagnosis is being found to resolve itself largely into a medical and mental problem. It is true that environment and training are equally important factors, but without the fair evaluation of the physical and the mental sides, other factors cannot be estimated in proper proportion. As in medicine, a patient may recover without treatment or diagnosis, or the physician may administer the proper treatment in spite of a wrong diagnosis, so in criminalistics, "reform" may take place without the reformer's help, or, empirically, with the reformer's help but without the fundamental cause of his career being discovered. Nevertheless, as in medicine, the majority of cases of delinquency require treatment based on diagnosis, and that diagnosis calls for all the help which the combined forces of sociology, medicine,

psychiatry and psychology can give. To this end, laboratories should be established in our courts and in our correctional institutions.

Statistics¹ of our Massachusetts penal institutions for the year ending Sept. 30, 1914, show the following figures:—

Of 25,820 prisoners sentenced during that time, 14,817, or 57.4%, had served more than one sentence. The total number of previous commitments was 92,443, showing an average number of over six sentences for each of the recidivists, or an average of over three sentences for each of the total number. These figures are taken in most instances from the unverified statements of the individuals themselves and represent a very conservative estimate of their previous court records. Such results, however, from methods of "reform" which have not been based on diagnosis are not encouraging.

As the result of study of 500 women— inmates of the Massachusetts Reformatory for Women—the problem has seemed to resolve itself into a question of permanent segregation, partial segregation and parole, rather than one of universal reform. The question becomes one of *treatment of the individual* rather than *punishment* for the kind of crime committed.

By permanent segregation is meant commitment to a "defective delinquent" or feeble-minded institution. This is for those defective individuals whose court record and history of immorality places them in a different class from the unsophisticated feeble-minded who represent at present the majority in our state institutions for mental defectives. Under the present "defective delinquent" law² they may apply for

* To be read at the Annual Meeting of the American Prison Association, Oakland, California, October 9-14, 1915.

release once during the year, so that in case of improvement or of adequate means of caring for them in the home, their release would be possible. Such an institution, although separate from the schools already in existence, might be under the direction of the State Board of Insanity, as are the other institutions for the feeble-minded in this state. Of the 500 women studied there were 24.8% who were candidates for such segregation.

By partial segregation is meant a *truly* indeterminate sentence. The indeterminate sentence, in general use, would be more correctly termed an "indefinite" sentence. Strictly speaking, an indeterminate sentence should be without *maximum* or *minimum*. When a truly indeterminate sentence is adopted, an individual can be treated until his "convalescence" is sufficient to warrant release and can be returned to the "hospital" in case of a "relapse" or "re-infection."

The present indeterminate sentence, so-called, in this state, while it is a great improvement on the previous fixed sentence, is not long enough in many instances to give the patients sufficient time to recover from their "indispositions," especially when the indisposition is based on an adolescent condition of instability which may require years of careful supervision and treatment to cure. While a truly indeterminate sentence would be ideal for the majority of offenders, it seems indispensable in controlling that class of individuals who are socially inefficient but cannot be permanently segregated. Thirty-eight per cent. of the 500 cases studied seemed to need such control.

The system of indeterminate sentence and parole is at present in operation in over thirty states in this country. Such a system, to be truly effective, besides controlling the individual for a sufficient length of time should be based on a complete sociological study including the mental, the physical and the social aspect.

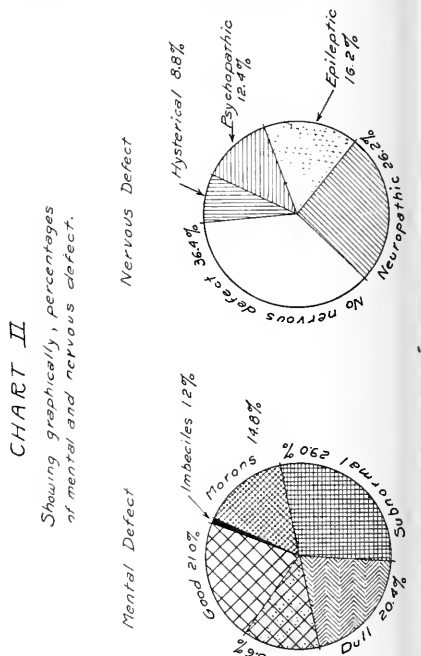

By parole is meant strict oversight outside the institution, with the understanding that the individual is to be returned if parole is violated. The parole class includes those who are eligible for release during the *present sentence*, which is a two-year indeterminate sentence for misdemeanors with a minimum of eight months, and a five-year indeterminate sentence for felonies, with a minimum of ten months. For these women the present system of legal procedure seems sufficient. This class includes 38.2% of the 500 cases.

The following charts explain in detail the basis for and the results of such a classification:

Chart I represents the general mental classification of the 500 women, while Chart II shows the same classification graphically. It will be seen that 16% show marked feeble-mindedness, while 29% show slight mental defect. This makes a total of 45% showing mental defect in some degree. 20.4% show poor native ability or are dull from some physical defect; 13.6% have

CHART I.
SHOWING GENERAL CLASSIFICATION OF 500 WOMEN.

	No Nervous Defect.	Neuropathic.	Psychopathic.	Epileptic.	Hysterical.	Total Number.	Total %.

Total %....	36.4	26.2	12.4	16.2	8.8		100%

fair intellectual capacity, while 21% have distinctly good intellectual capacity. Thus 34.6% show good or fair mentality.

In connection with these percentages it is interesting to compare Dr. Goddard's³ tabulation of mental defectives in various reformatories, which range from 28 to 89%.

"From these studies," Goddard says, "we might conclude that at least 50% of all criminals are mentally defective."

On the other hand, Dr. Bronner⁴ has found in 500 unselected cases in the Juvenile Court in Chicago that less than 10% were feeble-minded, while those normal in ability exceeded 90%.

A second classification of the same 500 women shows the following nervous defects: 36.4% of

the 500 show no mental aberration or defect of the nervous system; 26.2% may be classed as neuropathic; 12.4% are psychopathic; 16.2% give a history of epilepsy; while 8.8% show manifestations of hysteria.

As neuropathic have been classed those women who show general nervous instability without manifestations of hysteria or epilepsy and with no history of marked "control defect" or psychopathic tendencies. Included in this class are cases of migraine and those who, having had chorea or meningitis or some brain injury earlier in life, still show nervous manifestations.

The term, "psychopathic individual," in our classification, in its *specific* sense refers to these borderline mental cases which show no underlying symptoms of epilepsy or hysteria, but present symptoms of depression, excitement, "control defect" or ideas of persecution, which do not form complexes definite enough to be classed as psychoses. As a *general* term it has been used to denote the "institution incorrigible" in contra-distinction to the dormitory type of the institutionally amenable, and in this sense includes *all* who evidence "control defect," whatever the underlying cause. About 4% of these cases have been confined in hospitals for the insane at some time during their lives.

The epileptics are proving more and more an important factor in our population. This is interesting in view of Lombroso's belief in the close relationship between the "instinctive criminal" and the epileptic. In 400 cases studied previously,⁵ there was a percentage of 12; in this 500—the last histories being much more complete than the first—the percentage had increased to 16.2. In the last 112 cases, in which special attention has been paid to epilepsy, both in history taking and in the outside investigation, and which perhaps included a larger percentage than usual, the following results have been obtained: 20% (23 cases) gave an unquestionable history of epilepsy; besides these, 9% (11 cases) gave histories of probable epilepsy.

In the families of the 112 cases, 45 other cases of probable epilepsy were found, 29 of which were unquestionable. In 10 of the 23 cases showing epilepsy in the individual herself, there was an average of two other cases in each family. In nine cases showing no definite signs of epilepsy in the individual there was epilepsy in another member of the family. These last cases giving a family history of it usually showed some characteristic symptoms, such as migraine or marked irregularity in the psychological tests and much instability in behavior.

According to this table, 32% of the epileptics show good or fair mentality, while only 40 cases, or 49%, show mental defect. This will prevent at least one-half from being candidates for permanent segregation as mental defectives. The majority of cases are having attacks of minor epilepsy only, at present, while many give only a past history of it, although the resulting instability is still markedly evident in their behavior.

This, however, would interfere with their segregation as epileptics even if the state should provide custodial care for epileptics with a criminal record. This it does not do at present. It will be seen how important a truly indeterminate sentence is in controlling such exceedingly unstable and dangerous individuals. A large percentage of the women who have to be disciplined because they do not conform to the rules of the institution comes from this class.

Cases of hysteria have been diagnosed as such only when definite symptoms were present, such as attacks of unconsciousness following fright, or areas of anesthesia and the absence of reflexes (palatal and conjunctival), etc. It is interesting to note in the comparison of mental with nervous defect that the nervous defect apparently outweighs the mental; that is, 63.6% show some nervous aberration, while only 45% show mental defect. This makes one realize how closely associated the subject is with the psychiatrist's field.

The above classification has been made with the assistance of the assistant physician, Dr. Elizabeth A. Sullivan, who comes into close contact with the women through both the physical and mental examinations. We are indebted to her for help, both in classifying and in charting the results.

The next three charts—III, IV and V—represent the detail of the three classes into which the 500 women have been divided:—

CHART III.
SHOWING DETAILED CLASSIFICATION OF CLASS I (GROUPS A AND B) WHICH NEEDS PERMANENT SEGREGATION.

GROUP A.					
INSTITUTIONALLY AMENABLE.					
95 Cases or 19.0% of 500 Cases.

Moron			1	3	1
Subnormal			12	5	1
					18
Total	42	27	19	25	6
					119

Class I. This class (119 cases, or 23.8% of the total number) includes those who should be permanently segregated. Whether the cases are segregable or not has been estimated by judging the intellectual capacity, the social reactions and the resources for being protected in the outside world. As in insanity, a case has not been considered committable if it could be suitably cared for in the home. However, the fact that the woman has come to this institution usually

proves that the supervision was insufficient. Slight mental defect with a long court record has been considered as dangerous as marked mental defect with a short record, providing the outside resources for supervision have been the same.

All of the cases, however, which have been classed as "permanently segregable" show some intellectual defect. While it might be desirable to classify those cases as mentally defective which show social deviation but no apparent intellectual defect, in order to get custodial care for them under present conditions, still, for a differential study of causation, it would seem a great hindrance. If we are to judge by social record alone, 100% of the inmates of penal institutions are defective mentally. This, however, does not help us toward finding other factors equally important in "unclassified" cases which are at present being thrown on the general dump-heap of "defective delinquent."

Class I has been subdivided into two distinct groups, A and B.

(A) The first group includes those who are institutionally amenable and do not interfere seriously with the peace of any institution routine, in spite of various underlying factors, such as epilepsy, hysteria, etc. They can consequently be managed in large groups and can live in dormitories, both of which factors make their cost of maintenance a relatively small one.

The following case is illustrative of this group.

CASE 1. Class I, Group A. S. V. Age 26. Married; parents Italian; born in Connecticut. Offence.—Murder. No previous court record.

Family History. Father illiterate; earned \$7-8 a week in a bobbin shop (lowest possible kind of work). Mother living; can read and write; goes out by the day. Eight brothers and sisters; one brother at school for feeble-minded—an idiot.

No family court record.

Personal History. She attended country schools from 5 to 8 in Connecticut. Came to a mill town in Massachusetts where she attended school until 13; was never able to remember what she learned. She worked in mills from 13 to 18, then married. She had a bad reputation on the streets before and after her marriage. Her husband was alcoholic and gambled. He deserted her and four years later she obtained a divorce. She later remarried, having known her second husband a year and a half before marriage. He was a man of good reputation, became suspicious of her behavior and accused her of immorality. She took a revolver which was in the room and shot him.

Physical Examination. Well developed and nourished woman; has an endocarditis which is compensated; has gonorrhea and syphilis. She has attacks of unconsciousness (major hysteria) whenever anything goes wrong. Imagines she sees husband at night when depressed—is very unstable. However, no evidence of a psychosis has been found at any time.

Mental Examination. According to Binet, is eight years old mentally. Has attended school for six years, but reads and writes with difficulty. Knows no arithmetic. According to all tests she is a feeble-minded individual.

Disposition of Case. Although she has hysteria and is frequently in difficulty in the institution, still she is amenable, as far as her mentality will allow, and should be classified in the "institutionally amenable" group to be permanently segregated. This should be enforced even in the face of a possible pardon.

(B) The second group includes the institutional incorrigibles, who upset any institution routine. (Many of this class are scattered through our insane hospitals at present, under the diagnosis of "defective delinquent" and show no evidence of a definite psychosis.) They may show the same underlying factors as the previous group,—epilepsy, hysteria, etc., but the manifestations in their behavior are far more active. They exhibit violent temper, break windows and assault attendants and fellow prisoners. This class should be managed in small groups with the equipment of a psychopathic hospital, and the treatment should be a combination of education, therapy and discipline. They should be managed in groups not exceeding ten in number, and be cared for in separate rooms instead of in dormitories. This would, of course, increase the cost of their maintenance as compared with that of the previous group.

Havelock Ellis in "The Criminal," written as early as 1890, gives an interesting chapter on "Emotional Instability," in which he shows that the students of criminology have long been familiar with the "periodic explosions" and "wild fits of maniacal violence" among women confined in prisons. These, he thinks, might also be regarded as an "exaggeration or vicarious form of orgy." It is encouraging to know that the types which form our greatest problem at present have historic interest,—criminologically speaking.

Case 2 would be included in this class.

CASE 2. Class I, Group B. N. A. Age 22; single; colored; born in Massachusetts. Offence—Fornication. Previous offence, 1905,—Stubbornness; Sherborn 1912—Stubbornness.

Family History. Maternal grandfather and maternal uncles were excessively alcoholic. Mother is epileptic; father, living and well. There were eight children, six of whom died in infancy, causes unknown.

Personal History. Patient went as far as the second reader in school; can count to 100; was always erratic and destructive; has always had violent attacks of temper without provocation. Was committed to an industrial school in 1905 at 12 because she was unmanageable and stubborn. Had had for eight years previously received care as a State minor ward. At the industrial school made little advance in school work. Had a tendency to destroy things. Would torment little kittens, and was known to kill a chicken by pulling its head off. Was sullen and would torment and even threaten to kill her playmates. Was untidy about her room and person. Would build "nests" in her bed of any obtainable filth. When 14, was committed to a school for the feeble-minded. There she showed the same tendencies, and although she did good manual work, was very erratic and quick tempered. Was

excitable in the presence of men, dancing around, yelling, laughing and clapping her hands when she saw them; was easily excited to bad temper if criticized. Was cruel to other children, and several times struck attendants. When 17, was committed to a hospital for insane, where her behavior continued to be the same. Attacked other patients from jealous motives. Was very irritable, frequently scolding and threatening other patients. Six months later was transferred to another hospital for the insane. As her behavior there during six months apparently improved and her father was anxious to have her at home, she was released, only to be sentenced to Sherborn the following year on a charge of stubbornness. The same attacks continued, during which she was violent and sometimes threw furniture about and attacked officers. At the expiration of a two-year sentence, she was returned to the community, only to be sent back three months later on a new charge of fornication. This girl passed through five institutions in 10 years and was cared for by charity during a period of eight years besides. At the time of her commitment to the industrial school she had very little knowledge of immorality and was assigned to the "Innocent Cottage." When she returned the last time to Sherborn she stated with much glee that since going out she had learned to drink, and would now be as wise as her associates. She had visited the well known cafés. She had become pregnant during this time.

Physical Examination. A fairly well nourished and developed woman. A lesion in lung suggests an old tuberculous process. She has gonorrhea. Examination otherwise negative. Has had fainting attacks which were probably epileptic and occasionally has attacks of dizziness which are probably minor manifestations of epilepsy. The outbursts of temper undoubtedly represent psychic equivalents of the same disease.

Mental Examination. Attended school from 7 to 12, reaching only the second grade. Had further instructions at the industrial school and at the school for feeble-minded. Can do addition and subtraction, but is unable to do multiplication and division. Other tests for native ability show her to be a feeble-minded individual.

Disposition of Case. This woman, who undoubtedly requires custodial care, found no institution in the state where she could remain. She well represents the type which should be cared for permanently, although during her first sentence she would hardly have been a candidate for a defective delinquent institution. Some provision should be made for those cases with mental defect which are not insane, but which have abnormal mental traits besides their mental defect. Many of these individuals would become "delinquents" if not confined early enough, but earlier in their careers would be candidates for feeble-minded institutions on account of their mental defect even though they manifest abnormal mental tendencies.

The two groups should receive quite different treatment. That of Group A should correspond with the training already given in our model institutions for feeble-minded in Massachusetts. This should include educational and industrial work, with a fair amount of recreation, that their lives may be as useful and as happy as possible. Such an institution would be made, as far as possible, self-supporting. This would be a

great contrast to the present expenditure in the state, which is the result of irresponsible persons passing through our courts many times as they repeatedly return to penal institutions which, through their very nature, must have a high per capita cost. Their children, which they should never have been allowed to bring into the world, are being cared for, in the meantime, by the state.

CHART IV.

SHOWING DETAILED CLASSIFICATION OF CLASS II
(GROUPS A, B AND C) WHICH NEEDS A
TRULY INTERMEDIATE SENTENCE.

GROUP A.

INSTITUTIONALLY AMENABLE.

74 Cases or 14.8% of 500 Cases.

	No Nervous Defect.	Neuropathic.	Psychopathic.	Epileptic.	Hysterical.	Total Number.
Moron	5	1			1	7
Subnormal	20	30	6	8	3	67

GROUP B.

INSTITUTIONALLY INCORRIGIBLE.

60 cases or 12.0% of 500 cases.

Moron			1		1
Subnormal		1	6	3	10
Dull		5	7	4	16
Fair		5	7	3	15
Good		4	7	7	18

GROUP C.

RECIDIVISTS.

56 cases or 11.2% of 500 cases.

Subnormal?	4	2		1	7
Dull	6	9	4	1	21
Fair	6	4	4	2	16
Good	3	6	2	1	12
Totals	44	52	31	38	190

Class II. One hundred and ninety cases, or 38% of the five hundred, include those who are quite as much a menace to themselves and to the community as the first class, but who do not seem to us to present sufficient excuse in their mental defect or their social record, to be considered candidates for permanent segregation. The only way in which this class can be fairly treated, both as a protection to themselves and to the community, is by having a true indeterminate sentence which should enable society to keep them under supervision for a number of years. Parole might be granted whenever it seemed advisable, but the women should be kept under close supervision and returned to the institution if necessary.

Class II has been divided into three groups,—A, B, and C.

Group A represents the defectives who belong to the institutionally amenable class. This group corresponds to Class I, Group A, but although these all show at least slight mental defect, there is not, as stated above, a long enough

record of immorality, or the outside supervision is too good, to warrant the case being presented to a judge for permanent commitment.

Case 3 belongs to this class.

CASE 3. Class II, Group A. W. F. Age 52. French-Canadian. Offence.—Drunkenness. Seven previous arrests for drunkenness—four sentences, three probations.

Family History. One child died of spinal meningitis, another developed epilepsy after an attack of spinal meningitis. No other cases of alcoholism in family.

Personal History. Born in Nova Scotia, where she attended school from seven to twelve. She worked in a mill from twelve to twenty-one, then came to Lawrence with a cousin, and continued to work in a mill there. When twenty-four she married a man whom she had known for over a year. After they had been married for eight years and had been happy during that time, three of her five children died suddenly. She thinks that it was the loss of these children that made her begin to drink. Although her husband drank moderately, he was never arrested. She drank in neighbors' houses but was not arrested until she was forty-three years old. In spite of all her family and her priest could do she has drunk to excess continually since that time.

Physical Examination. Well nourished and developed woman with no venereal disease. Her teeth, which were in an unspeakably bad condition, have been attended to.

Mental Examination. According to Binet, she is less than 11 years old mentally. Attended school in Nova Scotia from 7 to 12 years of age, reaching the fourth reader. She thinks she was never smart in school and says she cannot do much arithmetic. She made one mistake in addition and failed to do subtraction, multiplication and division. Does not know the higher tables. Is unable to do easy practical problems. Other tests show her to be *sub-normal* mentally. Some of this defect, however, may be due to deterioration from alcoholic excess.

Disposition of Case. This woman, while quiet usually, is very disorderly when intoxicated. She has two daughters, both splendid girls, who, with the priest's help, have done their best to keep her straight. They begged to have her sent back as she went on a protracted spree as soon as she was released on parole. Her instability may be partly the result of the menopause. She has a very good home to which to return. Both of these factors considered with her slight mental defect, would prevent her from being a candidate for permanent segregation. It is necessary, however, to keep her under supervision until her period of instability may have passed. She, therefore, represents the need of a truly indeterminate sentence for slightly defective individuals.

Group B represents again the "institutional incorrigibles," but this group includes only those who show no intellectual defect and are, therefore, not considered permanently segregable. While segregation for this class may be possible at some later date, we do not believe that the classification of such mental types is sufficiently definite at present to permit it. The term "defective delinquent," used as vaguely as it is used at present, is not a definite enough

term for classification. It might easily include the majority of the inmates of our institutions. How are we to decide which ones are committable unless we use intellectual defect as a basis?

Case 4 is representative of Group B.

CASE 4. Class II, Group B. C. M. Age 37. Irish-American. Offence.—Drunkenness. Previous court record.—Drunkenness; 45 arrests; 16 probations; 29 sentences.

Family History. Negative so far as is known. Only one sister living, who is self-respecting and has a good reputation in the neighborhood.

Personal History. Born in Massachusetts, where she attended school until 13. Was always very nervous and hated to study. She finally left school because her younger sister went ahead of her. When 16, became intoxicated after taking something to drink for the first time from a young man with whom she had been associating. At the same time she acquired a syphilitic infection which became known to the family, causing much unhappiness. From that time on she has never been able to let alcohol alone for any length of time.

Physical Examination. A poorly developed and nourished woman. The Wassermann reaction for syphilis is negative, but there is a faint copper-colored rash on body. Bacteriological smear from cervix is negative for Neisser organisms. She has chronic gastric indigestion.

Mental Examination. According to Binet, she is 11 years old mentally. The results of tests for native ability are fairly good, although there is a great lack of concentration. During a previous sentence she was transferred to a hospital for the insane after a period of depression during which she attempted suicide. At other times she has disturbed periods when she will scream for several nights in succession, keeping everyone in the vicinity awake. During these periods of excitement she uses the vilest possible language, which she applies to everyone who comes near her. She throws everything around her room, although she has never been considered dangerous. She represents the manic-depressive type and even in her best periods is very unstable.

Disposition of Case.—She does not show sufficient mental defect to make her, in our estimation, a candidate for permanent segregation. She is, however, a dangerous woman in the community. She should be held on the indeterminate sentence, and if allowed out on parole, should be very strictly supervised. She belongs to the "institutionally incorrigible" group for partial segregation, i.e. a truly indeterminate sentence.

Group C includes those who have served three sentences or more and who show no mental defect or abnormality. Their record alone, however, has proved that they are incapable of caring for themselves in the community, and keeping out of trouble. Like all of the four preceding groups they are a great expense to the state, continually going in and out of institutions, seldom staying long enough for constructive work to be done with them and being, in the interim, a distressing element in the community. This group, in which mental defect or aberration cannot be considered a factor in the causation of delinquency, includes many who have been the product of wretched environment

or training. These two factors, however, have frequently been associated with *innate characteristics* which, although not criminalistic *per se*, in the environment in which the individuals have lived, have been partly responsible for the direction their careers have taken. On the one hand, one may find the non-resisting type, unable to resist customs about her, and craving sympathy and companionship as the normal individual does; on the other hand, one finds the aggressive type, with much more energy and physical temptation than it is possible for her to control or to express in her given environment. There are a few cases in this class in which no factors of heredity, environment or training can be found to account for the long record. However, we believe firmly that these cases show our own lack of understanding of mental and physical processes, and should be considered an "unclassified" group rather than be branded by the wholly inadequate and unfair title of "moral imbecile." As the science of criminalistics progresses, the "unclassified" group is rapidly becoming fewer in number—which is additional proof that such a classification was false.

Dr. Healey⁷ says with regard to this, after studying intensively over one thousand juvenile offenders, "We have been constantly on the lookout for a moral imbecile, that is, a person not subnormal and otherwise intact in mental powers, who shows himself devoid of moral feeling. We have not found *one*. Many cases have been brought to us as moral imbeciles, but they have always turned out somehow mentally defective or aberrational; or to be the victims of environmental conditions or mental conflict, and not at all devoid of moral feeling."

The following case (5) represents one of this type, who might first have been termed a "moral imbecile." Later, however, the underlying condition of minor epilepsy was discovered, which very likely was an important factor in causing her social instability.

CASE 5. Class II, Group C. H. P. Age 38. American; born in Massachusetts. Offence,—Forgery. Previous offences,—Forgery, 4 arrests; Larceny, 2 arrests; 4 previous sentences.

Family History. Parents were fairly well educated and respectable. They, with two brothers, have died. History otherwise negative.

Personal History. Attended school from 6 to 16, reaching the second year of High School. Took position as telephone operator at 17, and married three years later. Unknown to her husband, she forged several checks for small amounts without apparent incentive. After her husband's death, when she was 25, she continued this practice, working without known associates. The banks in all large cities have been warned against this woman, and her picture has been in wide circulation among the detective agencies.

Physical Examination. Fairly well nourished and developed. Has a positive Wassermann reaction but no specific history.

Mental Examination. According to Binet, she is

12 years old mentally (the highest age tested). Her intellectual capacity is apparently good, although she shows the irregularity frequently met with in the mental make-up of epileptics. She is decidedly neuropathic. Such a type might be considered "a moral imbecile" were it not for the later discovery of a history of epilepsy. This may well have been the underlying cause of her social instability.

Disposition of the Case. She belongs to the "recidivist" class and should be held on a truly indeterminate sentence, being kept under strict supervision if allowed on parole. The epilepsy in this instance is clinically a thing of the past and would not influence the immediate disposition of the case.

CHART V.
SHOWING DETAILED CLASSIFICATION OF CLASS III
WHICH IS ELIGIBLE FOR PAROLE.

GROUP A.					
HARMLESS DEFECTIVES.					
13 cases or 2.6% of 500 cases.					
	No Nervous Defect.	Neuropathic.	Psychopathic.	Epileptic.	Hysterical.
Moron					
Subnormal	7	2			1
					11
GROUP B.					
"REFORM" DOUBTFUL.					
70 cases or 14.0% of 500 cases.

Fair	15	2	1	3	1
Good	31	15	3	2	3
					54
Total	96	52	12	18	13
					191

Chart V represents 191 women, or 38.2% of the 500 who are eligible for parole, not necessarily because of the hopefulness of their cases, but because they present insufficient excuse for a longer sentence than is the minimum for each offence. With the first or second offence and no abnormal symptoms, one can only give them another chance, although it may be certain from their attitude that they will soon become members of the recidivist class.

This class includes three groups, A, B, and C.

Group A. Included in this group are a few defective individuals who are practically harmless and can be cared for sufficiently well in the home to allow them to go out on parole. Most of these are beyond the child-bearing period. This group, however, includes only thirteen individuals.

The following case illustrates this group:—

CASE 6. Class III, Group A. D. M. Age 49.

Married. Born in France. Offence,—Abortion; no previous record.

Family History. Unobtainable.

Personal History. Came to this country with her husband eight years ago. He is a stone mason and earns good wages. For the last few years she has apparently been doing illegal operations in the neighborhood. Her husband and she both deny this, but a girl who had had a miscarriage stated that D. had given her an instrument for that purpose. Another girl also made the same statement and the evidence was sufficient to convict her. While in the institution she has been quiet and industrious, although she is very childish.

Physical Examination. Fairly well developed and nourished. No venereal disease. Is at menopause, having had no periods for eight months.

Mental Examination. Is unable to read and write, even in French, although she attended a French school for four years. Other tests show her to be feeble-minded. She is very nervous and harmlessly excitable,—possibly a racial characteristic.

Disposition of Case. This woman has a husband who can provide a good home and is amply able to care for his wife. She is beyond the child-bearing age and will probably be harmless in the community. The fright of having been arrested and her husband's good sense will probably prevent any repetition of the former offence,—therefore she is eligible for parole as a "harmless defective."

A division has been made of the remaining 178 in this class into the two following groups: (B), those who appear so anti-social in their attitude and so wedded to undesirable habits of life that their return to society as responsible individuals seems a remote possibility; and (C), those who will probably prove responsible members of society. Although this is a wholly arbitrary division, it represents the opinion of those who have studied them over a period of many months and often years. We should like, here, to express our indebtedness to Miss Edith Stedman, who, at the time this classification was made, was in charge of the sociological department and was of great assistance in classifying the women from the social point of view.

Group B (the "reform doubtful" group) includes 70 women (14.0%). Case 7 is included in this class.

CASE 7. Class III, Group B. W. M. Age 17 Single; American, born in Massachusetts. Offence,—Larceny. No previous record.

Family History. Father, mother, sister, aunt and paternal grandfather had court records. All of these, as well as maternal grandmother, were excessively alcoholic. One cousin is at the Lancaster Industrial School and one at Lyman School for Boys. The home was a rendezvous for drinking and immoral people.

Personal History. W.'s father was a wanderer and deserted his family. Parents were alcoholic and fought continually. After the father left, the mother went to live with other men. Although W. is only 17, she is a sophisticated woman of the world and states openly that she thinks well of prostitution as a profession. She comes from a wretched neighborhood on the outskirts of a small city, where immorality abounds. She is attractive and in the

midst of adolescence, when popularity has unusual charm. She has known nothing in her life but immorality and apparently revels in it.

Physical Examination. General condition poor. She has gonorrhea, but so far has apparently escaped syphilis. The Wassermann reaction is negative.

Mental Examination. She attended public school from 7 to 14, reaching the fifth grade. She lost promotion twice on account of sickness. The results of her education are fair although her general information is very poor. Other tests show her intellectual capacity to be fair.

Disposition of Case. With seven years of immorality behind her and such temptation as she is bound to have outside, a girl of her inclinations, even if wholly removed from her former environment, presents little hope of a change in her habits of life. She has already become canny and worldly, and her good intellectual capacity seems to accentuate this rather than to lessen it. Although a change of attitude is always a possibility, in such a case as this, it is extremely improbable. We should class her among the less hopeful ones who are eligible for parole.

Group C. (the "reformable" ones) includes 108 women, or 21.6% of the total number. Case 8 is illustrative of this group.

CASE 8. Class III, Group C. O. M. Age 23. Married; Italian. Offence,—Adultery; no previous court record.

Family History. Father illiterate, worked in foundry in Italy. Mother dead, could read and write. One sister insane.

Personal History. Born in Italy; came to this country when 18, at the request of a cousin; was married 3 months later to an Italian who was immoral and abusive. After 9 months they were to return to Italy but he deserted her just before the steamer left. Because he did not send money to her in Italy, her father thought she could not be married, and when he found she was pregnant, turned her out of doors. She went to an aunt, where she met a man with whom she lived for two years. They returned to America after 7 months. He was good to her and supported her and two children which she had by him. (Her first pregnancy by her husband terminated in a miscarriage.) Finding herself in the same town with her husband some time later, she decided to return to him. (He in the meantime for three years had lived with another woman.) Her plan was to allow one of her children to remain with its father and to keep the baby herself. The husband insisted upon going to court, where they were all arrested. As he was the only one who could pay the fine of \$500.00, the other two served sentences for adultery. The sympathy of the court and probation officers was entirely with the woman rather than with the husband, who has a very bad reputation.

Physical Examination. A well developed and nourished woman with no venereal disease.

Mental Examination. Attended school in Italy from 3 to 12, reaching the fifth class. The results of her school advantages were rather poor. This may easily be due to the kind of school she attended. Although there may be some dullness, there is no evidence of mental defect. She is a good woman of the non-resisting type and without mental abnormality of any kind.

Disposition of Case. This case would seem to call for social adjustment. She certainly is eligible for parole, and it is a question whether or not she should ever have been sentenced to prison. She is consequently the reformable type of Class III.

Chart VI represents graphically the number of women included in each class. The average age of the three classes is as follows: Class I, 27.2 years; Class II, 31.1 years; Class III, 30.4 years.

It is interesting that as a class the most defective show the lowest average age. This would seem to be an argument against the classification according to age which has been suggested in various states,—their theory being that those women who are under thirty present the most fertile field for "reform."

Chart VII shows subdivisions of the three classes with the average of each division. It is interesting to note that the two classes showing psychopathic tendencies show a comparatively low age. Those in Group B of Class I average 26.4 years, as compared with 28.1 in the other group of the same class; while in Class II they average 23.7 years as compared with 29.1 and 40.4 years. The recidivists represent, as would be expected, the highest average, 40.4 years. The harmless defectives who are considered eligible for parole, have an average of 38.9 years, while the other two corresponding classes average 28.1 and 29.1 years respectively. Both the unreformable and the reformable groups in Class III average 26.4 and 26 years, respectively.

CHART VI

Showing classification of 500 women with reference to segregation.

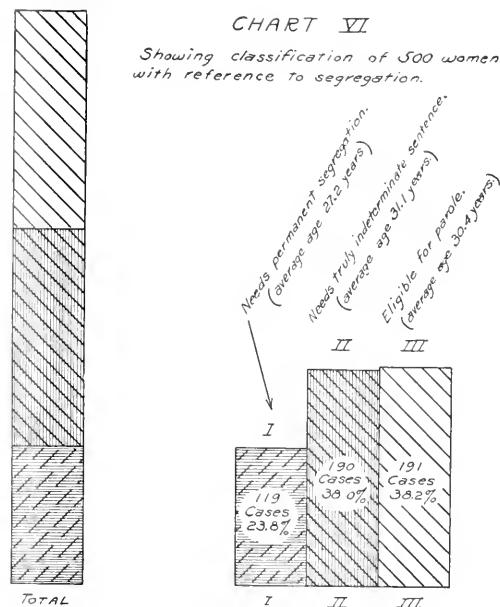

CHART VII

Showing subdivisions of each class.

- Class I Needs permanent segregation.*
- a Institutionally amenable defectives.
 - b " " incorrigible " (psychopaths)
- Class II Needs truly indeterminate sentence.*
- a Slight mental defect. (Institutionally amenable.)
 - b Psychopaths without mental defect. (Institutionally incorrigible)
 - c Recidivists (without mental or nervous defect)
- Class III Eligible for parole.*
- a Harmless defectives.
 - b "Reform" doubtful
 - c Reformable.

CHART IX

Showing nervous defect in each of the three classes.

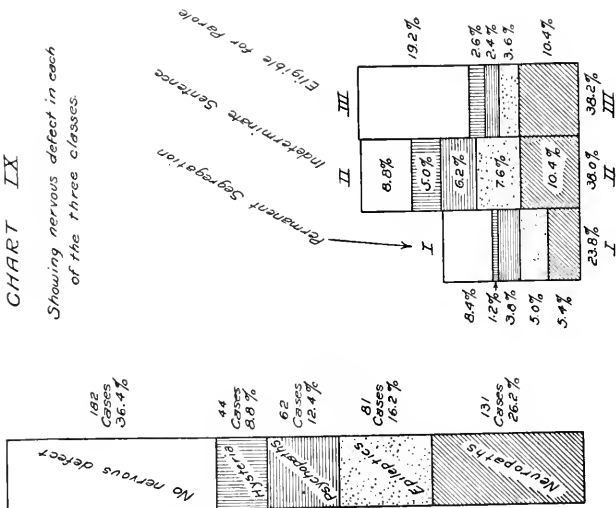

Chart IX shows nervous defect in the three classes. The highest percentage of nervous disease will be seen to be in the "Indeterminate Sentence Class."

CHART VIII

Showing proportion of mental defectives in each of the three classes.

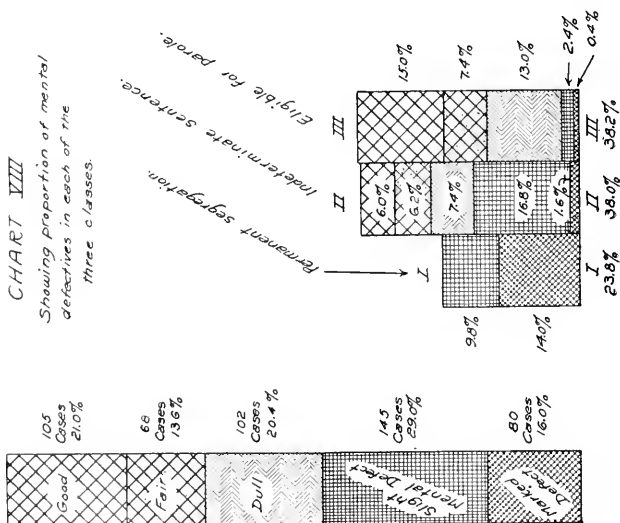

Chart VIII shows proportion of mental defect in the three classes.

CHART X

Showing percentage of venereal disease in each class.

Chart X shows the percentage of venereal disease. This chart shows from a different point of view the relative danger to the community of the three classes. Gonorrhea in the three classes is 92.1%, 79.4%, and 59.1%, respectively, while syphilis is 69.9%, 40.7% and 31.9% respectively. The total percentage of gonorrhea is 74.9 among the 500 women, while syphilis is 44.7%, with 9% more giving a doubtful Wassermann reaction.

CHART XI

Showing proportion of venereal disease in the subdivisions of the three classes.

Chart XI shows in detail the prevalence of venereal disease in the sub-divisions of the three classes. It will be seen that the cases with psychopathic tendencies lead the others in the proportion of disease which they have acquired.

Through the Sociological Department, it has been possible to study the women with regard to the relative number and character of arrests in the various classes. We are much indebted to the members of this department for the assistance which they have given in compiling statistics.

The average number of sentences and arrests of the three classes is as follows:—

CLASS I.		
	Sentences.	Arrests.
Group A.....	3.1	4.9
Group B.....	4.6	6.9
Class average.....	3.8	5.9

CLASS II.		
	Sentences.	Arrests.
Group A.....	2.5	3.4
Group B.....	2.2	3.3
Group C.....	4.5	7.9
Class average.....	3.1	4.9

CLASS III.		
	Sentences.	Arrests.
Group A.....	1.2	1.5
Group B.....	1.1	2.1
Group C.....	1.2	2.1
Class average.....	1.2	1.9

It will be seen that Class I has the highest class average, averaging 3.8 sentences and 5.9 arrests, Class II having 3.1 and 4.9, and Class III 1.2 and 1.9, respectively. This demonstrates the relative menace which the various classes are in the community.

The "institutional incorrigibles" with mental defect have a very high average as compared with

that of the amenable defectives. The "incorrigible" class without mental defect, however, does not show a relatively high average, being apparently less dangerous than the slightly feeble-minded of the same class.

The recidivist class naturally has a high average, but the fact that they have neither mental nor nervous defect makes them a greater problem, especially as there appears to be no excuse for their segregation.

Chart XII shows graphically the average number of sentences and arrests in the various groups of the three classes.

The average number of sentences and arrests according to the mental classification is as follows:—

	Sentences.	Arrests.
Imbecile	2.2	3.2
Moron	2.1	3.1
Subnormal	3.7	5.7
Dull	2.5	4.3
Fair	2.1	3.7
Good	2.1	3.7

The subnormal individual stands out here with the greatest prominence. Her intelligence seems great enough to increase her temptations, while at the same time her inhibitions are below the average. The dull individual has a higher average than the moron who, interestingly enough, is nearly on a par with those of fair and of good mentality.

CHART XII

Showing average number of arrests and sentences in the subdivisions of the three classes.

CHART XIII.

Showing average number of arrests and sentences in the three classes,—also, according to the classification of mental defect.

Chart XIII shows (1) the arrests and sentences in the three classes and (2) the same, classified according to mental defect.

The average number of sentences and arrests according to the classification of nervous defect is as follows:—

	Sentences.	Arrests.
No nervous defect.....	2.0	3.6
Neuropaths	3.9	6.2
Psychopaths	3.7	5.7
Epileptics	2.1	4.7
Hysterical	1.7	2.9

Chart XIV shows graphically such a classification.

Here it is noticeable that the highest average is in the neuropathic group, while the psychopaths follow closely—these two being considerably higher than any other group.

It may be of interest here to remember that the neuropathic group, besides cases of migraine, includes individuals who have had chorea or a meningitis or some brain injury earlier in life and still show nervous manifestations.

The offences, for which these women have been arrested, have been studied in a general way to determine the various kinds prevalent in the three classes. For this purpose four general divisions have been made:—

1. Alcoholism alone (21% of the 500 cases).
2. Offences against chastity, with or without alcoholism. This includes all offences which have a probable sex basis, such as stubborn child, vagrancy, common night walker, keeping disorderly house, lewdness, fornication, adultery, etc. (58% of the total number).
3. Offences against property, such as larceny, breaking and entering, forgery, etc. Many of these cases also have offences belonging to the first two classes. These are 15% of the total number.
4. All remaining cases, including offences against the person, such as abandoning children, assault, manslaughter, etc. These comprise but 6% of the 500 cases.

The following figures show approximate percentages of these four groups in the three classes:—

Offences.	Class I.	Class II.	Class III.	Average.
1. Alcoholism alone.....	18	16	28	21
2. Offences against chastity...	67	58	49	58
3. Offences against property..	12	21	13	15
4. Offences against the person, etc.	3	5	10	6

CHART XIV

Showing average number of arrests and sentences according to the classification of nervous defect.

The first interesting point is the apparently higher percentage of alcoholism in the third class. This is due, however, to the high percentage (71%) among the thirteen "harmless defectives" in that class.

Offences against chastity hold a very important place in the three classes (49.67%) and were actually at their height among the "reform doubtful" group of Class III. It is interesting to find the mental defectives showing such a slight increase in sex offences.

Offences against property appear highest in Class II, but actually show their highest averages in the groups where there is no mental defect. This is even more marked in cases of "offences against the person."

ADAPTATION TO PRESENT CONDITIONS.

The foregoing charts show the ideal disposition of the 500 cases studied. If laboratories could be established as clearinghouses in connection with our courts, many of these cases would never need to carry the unjustly imposed stigma of "prison," and could be sent directly to other institutions, where they would receive appropriate treatment.

In spite of the fact that such a laboratory has been started in our own municipal court in Boston, where excellent work is being done by Dr. Anderson, there is no defective delinquent or feeble-minded institution to which suitable cases can be committed. Until such an institution is established, these individuals must be cared for in the various reformatories to which they are committed. The resulting classification in this institution would provide for the care of three groups entirely separate from the main group.

Chart XV shows such a classification.

Group I would include the mental defectives of the institutionally amenable type; first, 14.6% with marked mental defect, and also those of the 21.8% showing slight mental defect, who would be a menace to the main group if their social record were too bad or their tendencies too undesirable. The less harmful ones might be kept with the main group to fill the easier positions.

Group II represents the psychopathic group or the institutionally incorrigible. This second group, 16.8% in the present classification, includes all psychopathic individuals whose tendencies are apparent in their behavior and who may or may not have mental defect.

Group III (the recidivists) includes those serving three sentences or more (11.2%) and might also include those women serving their second sentence (6.0%), if they, studied individually, should be considered a demoralizing influence for the main group.

The treatment of the first two groups has already been described. For the recidivist group, other than individual treatment, the chief need would seem to be some self-supporting industry,

CHART XV

*Showing classification necessary in institution.
I Amenable defectives.*

II Psychopathic group - with or without mental defect.

III Recidivists - without mental defect, or nervous disease.

IV Main group.

which should bring returns to the individual herself. It might eventually be possible to form a self-supporting industry which could be continued under partial supervision for women on parole.

If these three groups could be removed, the main group (IV) would then be composed of the first or second offenders without mental or nervous defect, presenting the most fertile ground for education and treatment. This group would not be handicapped then, as it must necessarily be at present, in a congregate building which admits of no adequate separation of groups and therefore no classification. Industrial, domestic and academic training can then be given those capable of receiving it and the discipline of the institution will not have to be suited to the window-breaking, assaulting types.

CONCLUSIONS.

If the criminal problem is one of treatment of the individual for his deficiencies rather than of punishment for the crime committed, the following fundamental provisions for the administration of such treatment are necessary:—

1. Adequate provision by the state for the permanent custodial care of all committable cases of mental defect whether or not they have a court record.

2. The establishment of laboratories in our courts and correctional institutions for the study and diagnosis of all offenders.

3. The equipment of all our institutions with facilities for classification and treatment of the various types which will remain even after the removal of the most defective. Such a classification will necessitate separate buildings, at least one of which should be equipped for hydrotherapy.

4. The adoption of an indeterminate sentence, which shall enable us to treat patients until they are able to return with safety to the community.

The physician has it in his power to do much towards educating the public to the need of fundamental measures of reform and towards counteracting the tendency toward superficiality of some enthusiastic believers in *universal* reform. His knowledge of mental and physical defect enables him to see more than the cross-section of the subject, which is represented by the population at present confined in our penal institutions, and to appreciate the social and economic waste which is the result of our past neglect of generations of inefficient in the community.

BLOOD PRESSURE DETERMINATIONS, URINARY FINDINGS AND DIFFERENTIAL BLOOD COUNTS IN A GROUP OF 662 YOUNG MALE ADULTS.

By ROGER I. LEE, M.D., BOSTON,

Professor of Hygiene, Harvard University, Cambridge.

THERE are apparently few absolute standards for the normal in clinical medicine. Our tentative standards are constantly undergoing readjustments. Furthermore, it seems true that physicians as a class are better acquainted with disease and its variations than with health and its variations. The physical examination of any large unselected group offers an opportunity of testing the standards now recognized for that group. In the physical examination of the entire freshman class at Harvard University, in addition to the usual visceral examination, observations were made on the blood pressure, systolic and diastolic, in both the recumbent and

standing positions; a complete urine analysis was made in each case; and a blood smear was taken, stained with Wright's stain and differential counts of the white corpuscles were made. This paper is based on the findings of a single examination.

There were 662 freshmen, the average age 18, average height 5 feet, 8 inches, average weight without clothes, 143 pounds.

Blood Pressure. Blood pressure determinations were made both in the standing and in the recumbent positions. The instrument used was that of Tycoos. The method was the auscultatory method. The diastolic reading was made at the beginning of the so-called fourth phase. These determinations are, of course, open to serious criticism on the ground of accuracy, but on the whole they correspond to the blood pressure determinations as taken as routine in most private and hospital practice. The average systolic pressure was approximately 120 mm. of mercury; the average diastolic pressure 80 mm. Arbitrarily, 140 mm. was fixed upon as the upper normal limit for systolic pressure and 100 mm. for diastolic pressure.

Increased Systolic Pressure. Eighty-five, or 12.8%, of the 662 presented systolic blood pressure readings over 140. The highest reading was 180. There were seven systolic blood pressure observations over 160, but there was only one case in which the systolic blood pressure was recorded over 150 both standing and recumbent. In 33 of the 85 cases the standing systolic blood pressure was over 140; the recumbent blood pressure was 140 or under. In 21 the recumbent blood pressure was over 140, while the standing blood pressure was 140 or under. In other words, considerable variation was found during the period of a single examination. While 85 showed a reading that might be interpreted as abnormal, in only 31 was the reading over 140 in both the standing and recumbent positions. It is of some interest that, while in general our readings followed the rule that the systolic blood pressure standing is somewhat higher than in the recumbent position, yet the reading was frequently the same in both positions, and occasionally, as in 21 of the 85 cases, the blood pressure was higher in the recumbent position than in the standing position. There were no systolic readings below 100 in both positions. An occasional reading in one position of 90 to 100 was found. The lowest reading was 80, in a youth standing who felt faint. A few minutes earlier and later the reading was 120.

It has been impossible to repeat the examination of this entire group. All of the cases of systolic blood pressures over 160, all the cases with diastolic pressures over 100, and all but two with an association of albuminuria and hypertension have been re-examined. Eighteen of the 31 cases with both systolic pressures over 140 have been re-examined, and of these 18, 13 presented a normal reading at the time of the

second or third examination. The five cases giving persistently abnormal readings were a case of probable nephritis, a case of obesity, one case of albuminuria and two cases with valvular lesions of the heart. It seems apparent, therefore, that too much stress should not be placed on a single systolic determination of over 140, for in our series 54 out of 85 with an abnormal systolic reading over 140 gave at the same time in some other position normal readings. Subsequently, 8 more of the 31 cases gave readings within the normal limits. Abnormal blood pressure readings on a single examination are not necessarily associated with any demonstrable visceral lesion, but seem to be associated rather with the nervous disturbance attendant on examination.

Increased Diastolic Pressure. The diastolic pressures were found to be much more uniform. There was comparatively little variation between the readings in the recumbent and standing positions. The average was 80. Only five cases had a diastolic blood pressure over 100. All these five cases presented systolic blood pressures over 140, but only one of them presented a systolic pressure over 160. Of the five cases who presented diastolic blood pressures over 100, no other abnormality was found in three cases. These three cases gave normal readings on re-examination. In one case with a reading of standing systolic 150, diastolic 110, recumbent systolic 160, diastolic 115, there was a diagnosis of marked obesity. Repeated observations confirmed these readings. The fifth case, with a standing systolic pressure of 164, diastolic 132, recumbent systolic 158, diastolic 122, showed a slight albuminuria with a negative sediment, without apparent cardiac enlargement and with a negative past history. These findings have been confirmed on several examinations and a probable diagnosis of chronic nephritis has been made.

This group would seem to illustrate the value of the determination of the diastolic blood pressure since the diastolic blood pressure is much less subject to variation than the systolic blood pressure. Of the entire group there is only one case that shows the completed picture usually associated with chronic nephritis, and that one case presented the highest diastolic pressure.

Abnormal Blood Pressure and Urinary Findings. Of this group of 85 cases, 9 (or 10.5%) showed albuminuria. The percentage of albuminuria in the total 662 freshmen was 5.1%. The incidence of albuminuria among the cases with an apparently abnormal blood pressure is approximately twice as great as in the total group. In only one case with albuminuria was the systolic pressure in either the standing or recumbent position over 160. This is the case of probable nephritis. In two cases there were no further observations. One case had a persistently high systolic pressure and albuminuria, but he also had a chronic endocarditis, which

might well have explained the high blood pressure. Of the remaining five cases, the albuminuria cleared up in three and the increased blood pressure in five cases. In only one was there a persistently slightly increased blood pressure and albuminuria. Two of the cases with an abnormal blood pressure showed a temporary glycosuria. In both these cases on re-examination the sugar disappeared from the urine and the blood pressure readings were within the normal limit.

Abnormal Blood Pressure and Other Abnormal Findings. In seven of the 86 cases, a definite valvular lesion of the heart was found. One of these cases also presented albuminuria. In these cases it seemed reasonable to associate the increased blood pressure with the valvular lesion. In all the seven cases the heart was apparently compensated. Four of the seven had the classical signs of aortic regurgitation. In two more cases showing an abnormal blood pressure, apparent cardiac enlargement was found without adequate cause, either in the history, urinary findings or other examination.

In one case a slight goitre was present, which may or may not have been the cause of the apparently abnormal blood pressure. Another case of obesity presented a persistently high blood pressure. There are, then, 22 cases with an abnormal blood pressure reading which are associated with other lesions, leaving 52 cases in which no other lesions were found.

Albuminuria. Thirty-four of the 662 freshmen (or 5.1%) showed albumen in their urine. These 34 have all been re-examined and on the second examination ten of them were free from albumen, and the condition seemed transitory. In three other cases the albumen was definitely orthostatic inasmuch as repeated examinations showed that albumen was constantly absent in the early morning and fairly constantly present during the day. The amount of albumen varied. A positive test depended on a definite ring with nitric acid. Careful sediments were examined and casts were found in only four of the 34 cases. Three of those four subsequently became free from albumen. Eight of the 34 (or 20%) showed a systolic pressure over 140. Eighty-five of the total number examined (or 12.8%) showed a high systolic blood pressure. There was only one diastolic pressure over 100. This was the case of presumable nephritis. Three of the 8 cases with a slightly increased blood pressure, which was in only one case over 160, showed no albumen after the first examination. In none of these cases was there any other evidence of cardiac enlargement.

During the same time 275 other members of the University were examined in a similar way. Of these, 10 (or 3.6%) showed albumen, and of these 10 only one showed a systolic blood pressure of over 140 on a single observation. There were no diastolic pressures over 100. The urinary sediments from these cases in no instance showed casts and in no case was there

any evidence of cardiac hypertrophy. The majority of these cases were not carefully followed, but in two instances the albumen was temporary, in one it was apparently orthostatic, and in one it was always present, and had been known to be present for at least 10 years.

Glycosuria. Five cases showed sugar in the urine; in two cases the sugar immediately cleared up and has not reappeared. In one case there is occasionally a slight reduction. Two cases, however, showed persistent glycosuria even after moderate restriction of the diet. One case required very strict dieting before he became sugar-free: the other case became sugar-free on a moderate restriction of carbohydrate foods.

Glycosuria is much less common under the conditions of our examination than albuminuria. In two cases it seemed transitory and in one probably so. In two other cases the glycosuria apparently indicated some more or less permanent defect in metabolism.

Blood Examination. Blood smears were made in every case, and differential counts of the white corpuscles were made in 564. The main interest was to determine the presence of leucocytosis, lymphocytosis or eosinophilia. Recent reports by Cabot and others of lymphocytosis made us suspect that lymphocytosis would not be uncommon in the usual conditions of health. The usual, although somewhat unsatisfactory, classification of polynuclear leucocytes, lymphocytes, transitional cells and eosinophiles was followed. Only five cases presented a polynuclear leucocytosis of over 75%. Only four cases showed an eosinophilia of over 5%; the reasons for these were not apparent. Seventy-three cases showed a lymphocytosis of over 50%, but in no instance was the lymphocytosis over 60%. In 158 cases the lymphocytes were between 40 and 50% of the white cells. In other words, 231 of the 564 cases showed a lymphocyte count between 40 and 50%. It was a matter of surprise that no greater variations were found. The red cells were essentially normal in every case.

The result of our examination of the blood smears showed that there is little variation from the usually accepted standard in the differential count in the healthy young male adult. Our findings rather corroborated the view now generally held that the lymphocytes frequently approach 50% of the white corpuscles in the normal blood, and not infrequently, in 73 cases out of 564 (or nearly 13%), are over 50% of the white corpuscles; but in none of our cases did they exceed 60%.

General Conclusions. Among young male adults in the usual condition of health a single determination of the systolic blood pressure frequently gives readings that are regarded as abnormal according to the usual standards. This deviation from the usual standard may be considerable and may be present on several occasions. In the absence of other abnormal find-

ings moderate increase of systolic blood pressure seems to be of no significance. The diastolic blood pressure is much less subject to variation and is of considerable value in offering a control on an abnormal systolic pressure.

Albuminuria was present in 5% of this group, and in only one case was there additional evidence of a true nephritis. Albuminuria in young male adults may be permanent, orthostatic or transitory, and is apparently of no serious significance.

Glycosuria is unusual and in one case particularly, and apparently in another, was more than transitory and seemed associated with disturbed metabolism.

The differential counts of the leucocytes of the blood in this group confirm our accepted standard for the normal.

NOTES ON GASTRIC AND DUODENAL ULCERS.*

BY CHRISTOPHER GRAHAM, M.D., ROCHESTER, MINN.

THE questions often arise: Are there any symptoms or a group of symptoms whereby we may reasonably locate peptic ulcer? Do clinical histories, as ordinarily taken, give satisfactory evidence as to whether the ulcer be high or low? When the full evidence is before us we often feel that the picture is reassuring, and when reviewing histories taken by other clinicians, we find symptoms repeated so frequently that we have hopeful moments. However, after reviewing the histories of our own cases from 1906 to 1915, we cannot find any pathognomonic symptom, or combination of symptoms that clearly gives the coveted assurance, and we are forced to conclude that he who meets defeat again and again, in attempts at ulcer location will in time, even when the symptoms have met most of his requirements, come to feel less sure in his diagnosis than is comforting.

The clinical diagnoses in our series of approximately 1300 cases of operatively demonstrated duodenal ulcer during the years mentioned above have run about as follows: There were 702 (54%) cases primarily called duodenal ulcer, while 323 (24.8%) were classified as gastric ulcer. In another group of 107 (8.2%, repeated) gastric or duodenal ulcer was given as the secondary diagnosis, or was considered equally with the lesion in question as the cause of the complaint. One hundred seventy-five cases (13.5%) were primarily considered gall-stones (5% gall-stones alone), or gall-stones entered largely into the diagnosis (8.5%).

In 64 cases (5%) appendicitis (1% appendicitis alone) entered largely into the diagnosis, while cancer was considered in 1½%. About 1% were quite unclassified.

Among the 450 cases of gastric ulcer oper-

* Read before the Marshfield Clinical Meeting, Marshfield, Wis., June 30, 1915.

actively demonstrated, 248 (55%) were classified as gastric, 119 (26½%) as duodenal, and 31 (6½%, 19 gastric and 12 duodenal) in which the gastric diagnosis was placed second. The gall bladder was primarily considered diseased in 40 (8.8%) cases and in 5% this was the only diagnosis made. Cancer was considered present in 4.8% of the cases, appendicitis in 1.7%, those not classified about 2½%. From these figures it will readily be seen why one hesitates in many cases to attempt to make a possible diagnosis as to the location of the ulcer. It is not a difficult problem to diagnose the presence of a peptic lesion, but it is quite difficult to determine whether the lesion is gastric or duodenal.

We have fallen into the way of roughly dividing gastric complaints into those of regular and of irregular types, and also of considering a gall bladder type. However, one must keep in mind extrinsic causes, such as gall-stones, appendicitis, and tuberculosis. These may give quite the regular gastric syndrome, and gastric symptoms be the chief complaint for which relief is sought, or they may very often give an irregular history, which confuses and leads to provisional diagnoses.

The following clinical syndromes are worthy of consideration:—

1. *The regular type of duodenal ulcer* is looked upon as that in which the pain or distress comes within two to five hours after meals, accompanied by gas, sour stomach and vomiting, one or all appearing about the same hour, and continuing until the next meal, or until food, an alkali, vomiting or irrigation brings comfort by relieving the acid state. These symptoms are repeated with certain uniformity each day for days, weeks or months, and then there is an intermission of perfect ease, or at least a marked remission ensues. These periods of attack and intermission may come and go for years, the only change, perhaps, being an increase in severity until the time comes when complications have altered the gastric movements and functions.

2. *The regular gastric type*, as we prefer to consider it, has the same periodicity and the same group of symptoms, though not so clearly cut as in the duodenal lesion, but, as we have shown, in at least one-fourth of the cases the difference is quite indistinguishable. Pain or distress comes sooner after meals, does not continue so clearly to the next meal, may cease for a time to begin again before the following meal, and is often eased by food, though not so often nor so clearly as the pain of duodenal ulcer. Fear of food-pain is more often noted. Food in small amounts gives ease, while in larger amounts it gives pain. Hunger-pain is not so clear cut, and not so frequent, because the pain may pass before mealtime arrives. Careful diet seems to give more relief than in duodenal ulcer, unless complications are present. Sour food is not so troublesome in the high as in the low ulcer, and the position of the body as well as

physical activity plays a more important role in the gastric than in the duodenal cases. A definite intrinsic gastric complaint runs throughout the history, though the features seem less clear cut than in duodenal ulcer, and one feels a greater lack of certainty in the diagnosis. However, the fact remains that the final diagnostic figures in this series hold clearly as well in the gastric as in the duodenal types.

3. *The irregular peptic ulcer type* of history has lost the distinctive time of onset of symptoms and their control. We find such histories in cases of obstruction, perforation with adhesions, hour-glass stomach, saddle ulcer, lesions of large areas, or any condition where function and movement are limited.

Intermissions or remissions are fairly constant, but not so well defined as in uncomplicated ulcer found low, or even usually those well above the pylorus. This type of history does not give that daily distinctive time of onset and control of symptoms which we expect to see during the period of an attack. They do not run that clear cut course, yet when considered day by day, and week by week, we discover in the so-called irregularity a certain definite course which clearly points to an intrinsic lesion of the stomach. Day by day the average is quite the same, though usually, the hunger-pains, food ease, and hemorrhages are less definite. However, pain, vomiting, distress, gas and sour eructation are the constant results of food intake, from which more or less relief is experienced by careful diet, alkali, irrigation or vomiting. These factors are always first in the patient's complaint, and are the ones most considered in the diagnosis. This irregular complicated type of history may be manifest from the first onset of symptoms, but often the early history, carefully developed, brings out the clear cut typical history which supplies the final diagnostic point.

Histories in cases of high ulcer tend earlier to this irregular type, those of pyloric and duodenal ulcer less often, and then usually when obstruction or other complications have intervened. Thus, in the so-called irregular types, we incline to the diagnosis of gastric rather than of duodenal ulcer, or we look for extrinsic causes. When gastric symptoms predominate we must always bear in mind these extra-gastric causes, whether they be general diseases or local conditions. At times the course of these extra-gastric lesions may be so typical of ulcer, even to the extent of hemorrhage, that ulcer is diagnosed, unconditionally. Fortunately, however, the day-by-day symptoms in these cases vary so much,—today this effect, tomorrow quite different, again a day entirely free, and through it all no change in diet or surroundings,—that one catches the hint and guards the diagnosis. With patients complaining of gastric distress it is necessary to be constantly on guard, always ready to differentiate the extrinsic causes that simulate the regular ulcer type, as well as to differentiate

those that seem to be of the irregular ulcer type, but are also as surely due to extrinsic causes. It is among the symptoms due to an extra-gastric condition, that many difficult diagnostic battles are fought and lost, or but partly won, and it is these same difficult battles that have taught us to hesitate before making a too spirited diagnostic charge at the real enemy.

When reading duodenal histories one is apt to be impressed with the array of so-called regular histories, and to feel that ulcers higher up are not nearly so clear cut. Yet in going over the histories from 1906 to 1915, we discovered that 72% of duodenal cases gave fairly regular symptoms and that 71% of gastric cases gave the expected syndrome, or were so clearly gastric that little hesitancy was felt in making a diagnosis.

Pain is the one constant diagnostic factor in all peptic ulcers. Less than 1% of patients are recorded free from pain. The character of the pain has few if any distinguishing points, and is described as: Distress, aching, burning, gnawing, pressing, boring, sharp cramps, colic, etc. It runs a similar course in all ulcers, though it resembles the pain in gall-stone cases more frequently in the duodenal group. The time of pain has some distinctive diagnostic significance. In the duodenal ulcers the pain came $\frac{1}{2}$ to 2 hours after food in 23% of cases, and 2 to 5 hours in 77% of the cases. In gastric ulcers the time limits of $\frac{1}{2}$ to 2 hours included 50% and 2 to 5 hours an equal number. In 20% of the duodenal and in 19% of the gastric ulcers the time of pain was not recorded. Eight per cent. of the patients with duodenal ulcer and 19% with gastric ulcer had pain within $\frac{1}{2}$ to 1 hour after eating.

Pain at night appeared to be more decidedly frequent in duodenal ulcer, while ease from posture (lying down) seemed decidedly more frequent in gastric ulcer. However, the final analysis gives 14% of the patients with duodenal ulcer and 10% of those with gastric ulcer having pain at night. Postural ease was noted in 8% of the duodenal and in 9% of the gastric cases. These figures correspond much more closely than one would suppose from impressions gained in history writing.

Continuous pain from the beginning of symptoms was mentioned in 4% of the duodenal and 9.5% of the gastric cases. Tenderness to touch was recorded in 41% of the duodenal and 40% of the gastric histories.

The location and radiation of pain was noted as follows: Of the duodenal ulcers 49% were well confined to the epigastrium, 52% of the gastric were similarly located. Those with radiation to the back ran 24% duodenal and 22% gastric. In the diagnosis gall-stones were considered certain or were given first place in 13% of the duodenal and in 9% of the gastric cases.

Radiation to the left epigastric area occurred twice as often in gastric (10%) as in duodenal cases (4%). The percentage of radiation to the

abdomen and fossae was quite similar (9.5% duodenal, 9% gastric). Radiation to right epigastrium was present in 6.6% of the gastric and in 13.7% of the duodenal cases. Therefore, tenderness to touch, radiation of pain, and the patient's ability to locate his subjective pain gave little basis upon which to arrive at a differentiation. The pain, as described by the patient, had much the same character in both the gastric and duodenal type, so much so that it gave but little clue to the location of the lesion. However, when ulcers were high there was some diagnostic foundation in the patient's ability to locate his subjective pain. In some instances the pain was quite to the left side or even well under the left arch.

Vomiting was recorded as occurring in 79% of the duodenal and in 82% of the gastric ulcers, while gas was present in 77% of the duodenal and in 94% of the gastric. With the vomiting and gas, sour gastric contents was quite constant in both types, though more troublesome in the gastric.

Control of pain, whether the lesion was in the duodenum, or above, ran quite the same and was as follows:—

Food or drink, or both, eased pain in 75% of duodenal, and in 66% of gastric ulcers. Vomiting and belching of gas had less distinguishing percentages, both giving marked ease. Ease from belching of gas in each was less permanent than vomiting. However, gas formation and belching were more persistent in patients with ulcers of the pylorus.

The effect of alkalis was practically the same wherever the location, *i.e.* ulcers above the pylorus were about as frequently (33%) eased as those in the duodenal area (38%). Irrigation gave about the same results no matter where the lesion (11% in duodenal and 9% in gastric), the advantage lying slightly in favor of the duodenal location.

Gastric hemorrhages may be of some diagnostic aid. In this series, history of hemorrhages by the mouth was recorded in 18.5% of duodenal and in 25% of gastric cases. Blood by the bowels was similarly recorded in 18% of duodenal and in 24% of gastric cases.

Perforation ran about equal in both classes (duodenal 28.7%, gastric 26%) and of those that perforated, the pancreas received the perforation in 17% of the duodenal and in 25% of the gastric cases. Pain to the back, which more or less simulated gall-stone radiation, ran about equal (24% duodenal, 22% gastric) in the two conditions, all cases considered. This clearly accounts for the wide range of suggestion of gall-stones in our cases with gastric lesions.

The effect of diet as usually prescribed for, or undertaken by, the patient, varied little so far as the comfort it brought to the two types of cases (20% duodenal, 22% gastric eased); but the amount, quantity, and kind of food at times so modified the gastric syndrome that their care-

ful consideration helped in the differential diagnosis.

Though apparently so nearly similar are duodenal and gastric ulcers in their final analyses, there are some points that aid in their differentiation. In the whole picture, the coming and going of symptoms are not so distinctly seen in gastric ulcer. The pain in the gastric form often comes earlier after food (within 1 to 2 hours, in one-half the number), and frequently ceases in a short time, or before the next meal. It may return after a brief intermission, to be eased by the next meal, or the distress is such that food is refused lest pain be increased. This is more often the case in gastric than in duodenal ulcer, unless complications are present. Certainly when adhesions and perforations are present in any ulcerative lesion, and clearly more so in those well above the pylorus, pain may begin sooner after food intake. This *early* pain is due apparently to peristaltic movements,

tugging at the sensitive adhesions, quite as much or more so than to any acid fluid acting upon the chronic ulcer or open wound.

In gastric ulcer a small amount of food more frequently gives ease, while large amounts give immediate pain, and thus, patients with gastric ulcer are not so apt to depend upon food to give ease, or to so spontaneously state its comforting effect. Acid foods trouble gastric cases less than they do duodenal (and pyloric) cases.

Position is also a greater factor in high than in low ulcer. Pressure, as bending over the arms of a chair, or doubling up on the thighs, gives ease more frequently or prevents pain setting in so severely. Lying on the back or side, or on the stomach, is more often found comforting in gastric ulcer. Therefore, *night* pain is not so frequent: (1) perhaps because obstruction is less liable in gastric cases (26% duodenal, 10% gastric), or at least the narrow-

ing is less; (2) because the ulcer by the position assumed is relieved of the acid's immediate presence; (3) by the high location of the ulcer the irritating fluid falls below the ulcer or is pressed away from it; and (4) peristalsis eases when the body is at rest, or when pressure is applied. This differential point of position is much more clearly felt in history taking than seems apparent in our final percentages and should, we think, be considered.

Ulcers located toward the greater curvature, ulcers with extensive surfaces, and many saddle ulcers tend to more constant symptoms, thus exhibiting the symptoms of chronic complicated ulcers situated elsewhere. Perforations and adhesions seem more often to affect gastric ulcers than duodenal and, as before stated, peristalsis plays a more important part in pain production when adhesions limit the normal movements.

Eruetion of burning sour-water (heartburn) or of tasteless or salty water (water brash) is more often mentioned by those who have gastric lesions. Also, bloating and its distress are more frequent in the cases of higher ulcers.

Pain that comes immediately or soon after food intake seems to point to cardiac, fundic or other extensive ulcerations, perforations, adhesions or obstructions. Coarse and large amounts of food may increase pain in any ulcer, but more constantly in gastric rather high in position, and high ulcers often seem to have periods of shorter duration (1 to 5 days) and shorter intermissions, or remissions which show a lighter grade of symptoms and tend to constant complaint. Thus the case may run month by month, pain earlier, not constant and decided food or soda ease; all symptoms varying somewhat as the amount and kind of food varies, giving one the impression of irregularity yet constantly of gastric origin. Duodenal or pyloric ulcers more often run an exact course day by day for days or weeks with decided food ease.

However, each case necessarily calls for its own careful consideration, because no symptom, or group of symptoms, can more than suggest location and often, as our histories show, the gastric case may have the pure duodenal syndrome and the duodenal case may quite as clearly give the gastric type of symptoms. The diagnosis of a gastric lesion being made, the question of its exact location is not paramount. How best to treat the lesion and conserve the patient's health is the vital point.

CASES OF INFECTIOUS DISEASES reported to the Boston Board of Health for the week ending Sept. 21, 1915: Diphtheria, 57, of which 16 were non-residents; scarlatina, 17, of which 5 were non-residents; typhoid fever, 18, of which 4 were non-residents; measles, 8; tuberculosis, 61, of which 3 were non-residents. The death-rate of the reported deaths for the week was 13.47.

Clinical Department.

THE USE OF CALCIUM IN THE TREATMENT OF EPILEPSY.*

By JOHN BRYANT, M.D., BOSTON.

[From the Neurologic Out-Patient Department, Massachusetts General Hospital.]

My share in the study of this unfortunate class of epileptics to which Dr. Clymer has referred, is an inquiry into the physical characteristics of the epileptic with regard to type, and into the relationship (if any) between disorders, organic or nutritive, originating in the gastro-intestinal tract or in the fuel supply, on the one hand, and on the other, manifestations of ductless gland disorder and disturbance of function of the nervous system.

One phase only of the observations in progress can be referred to in the brief time at disposal, and this concerns the metabolism of calcium. In addition to faulty heredity, overwork and undernutrition or malnutrition, seem with considerable frequency to precede the onset of the attacks. Prolonged periods of malnutrition at once raise the question of dietary errors.

The time has gone by when it is complacently assumed that man ingests sufficient of the necessary mineral elements, no matter what may be his diet. It is well known that many poverty stricken, such as white bread and potatoes, are very deficient in calcium. Bunge, in his "Physiologie," some years ago drew attention especially to the increasing use of alcohol and sugar as factors in the production of a calcium deficiency in the dietary of the poor, arguing that these substances satisfy appetite which otherwise would impel the ingestion of a larger proportion of calcium rich vegetables or fruits for the obtaining of the coveted sugars. It is also known that analyses of brain substance have demonstrated the presence in this tissue of less than the normal amount of calcium, in certain disorders marked by hyper-irritability of the nervous system; and recently Foote¹ has demonstrated a decreased calcium content in the femur of an idiopathic epileptic. Thirdly, calcium has been used in such explosive conditions as tic and tetany with reported success, but hitherto apparently only to a limited extent in the treatment of epilepsy. Therefore it has seemed worth while in the course of other observations to see what effect, if any, its use would produce.

The results have in some cases been sufficiently striking to warrant mention in the hope that they may be checked up by other workers. The official syrup of calcium lactophosphate has been used in doses of 5i-ii t.i.d. either a.c. or p.c. Calcium bromide could, of course, be used, and it is planned to employ this later, but at first the calcium preparation was simply added to pre-

* Presented at a clinical demonstration at the Massachusetts General Hospital, June 8, 1915.

¹ Foote: BOSTON MED. AND SURG. JOUR., 1915, Vol. clxxiii, p. 392.

existing medication without other change in the treatment. When thus used the calcium appears to produce at least three effects, in favorable cases; it promotes sleep, it decreases nervous irritability, and it acts in some measure as an antidote to bromide acne.

Favorable cases are those of *petit mal* type, which, according to Dr. Taylor, have hitherto been the least affected by bromides. Members of the clinic staff, familiar with the condition of some of the cases in question for months, if not years, before the present experiment commenced, have expressed themselves as struck by the sudden improvement in general appearance which has been displayed. Nearly all cases have shown some benefit, which may, of course, be partly a psychic reaction; but in a few cases it has been decidedly dramatic to note in the course of two or three weeks the change from surly and depressed irritability to a condition of apparent cheerfulness and regained faith in the future.

Calcium is not presented as a panacea. It may not cure any case, but it at least can be said that when added to existing only partly successful treatment by bromides, it has in some cases produced results sufficiently encouraging to make it seem desirable to mention its employment and possible value.

In closing, it is desired to focus attention upon a broader question related to calcium metabolism. It has been held that such manifestations, as for instance chorea, migraine, tic, tetany, and epilepsy, are absolutely unrelated disease entities. Proof is lacking. It is, on the other hand, not impossible that proof may be forthcoming to show that these diseases are, at least in some cases, merely different expressions of an underlying abnormality common to all, bearing to each other somewhat the same relation as do the visible and varying wave crests to the sea beneath. Three facts suggest that a lack of calcium may be such a common underlying factor in more than one of these conditions: many diets are deficient in calcium, calcium is deficient in the brain tissue of those afflicted with certain explosive manifestations, and some of these diseases have been markedly relieved by the administration of calcium.

These facts make it advisable to determine the extent to which a lack of the mineral constituents of the diet, and a lack of calcium in particular, may underlie the manifestations, not only of epilepsy, but of various other explosive disorders of the nervous system which have hitherto been looked upon as disease entities.

WALTHAM TRAINING SCHOOL GRADUATION.—

The annual graduation exercises of the Waltham Training School for Nurses were held in that town on September 24. The principal address was made by Dr. Alfred Worcester, and Dr. C. Benjamin Fuller presented diplomas to a class of 17 pupil candidates.

SYNCHRONOUS INSPIRATION AND SYSTOLE IN A PATIENT EXHIBITING EQUAL RESPIRATORY AND PULSE RATES.

By PAUL DUDLEY WHITE, M.D., BOSTON.

[From the Medical Service of the Massachusetts General Hospital, Boston.]

An Italian boy of six years of age with partial heart block and probable miliary tuberculosis, was under observation for three weeks (April 7-26, 1915). Involvement of the lungs was indicated by the Roentgen ray. He showed on at least six occasions on different days equal rates of respiration and pulse with synchronous inspiration and systole. In the record made with the Mackenzie ink polygraph (Fig. 1) inspiration, represented by the downstroke on the respiratory curve, precedes the pulse at the wrist, represented by the upstroke on the radial curve, by a little more than one-fifth of a second. Deducting from this interval the length of time from the beginning of systole to the appearance of the pulse at the wrist, which is about 0.18 second, the onset of systole is seen to be almost synchronous with the onset of inspiration, following it by a small fraction of a second. This interval varied in different records taken, at times systole preceding inspiration by a like interval. Sometimes, when an irregularity of the block occurred (3 to 1 and 3 to 2, instead of 2 to 1) the radial pulse became irregular but the respiratory rhythm continued unchanged. Similarly, when the breath was held the pulse kept on at a steady regular rate; at such times a loud systolic murmur ordinarily heard over the precordia, disappeared, to reappear when the patient resumed his respiration. An electrocardiogram shows clearly the 2 to 1 heart block present (Fig. 2).

FIG. 1.—Simultaneous tracings of radial pulse (lower curve) and respiration (upper curve). In the respiratory record, downstroke = inspiration, upstroke = expiration. Time interval = 0.2 sec.

FIG. 2.—Lead I of electrocardiogram showing the presence of 2 to 1 heart block. The blocked auricular complex *P* falls on the upstroke of the ventricular deflection *T*. Abscissa, 0.2 sec. Ordinate, 10-volt.

Reports of Societies.

CLINICAL CONFERENCE OF THE NEUROLOGICAL INSTITUTE, NEW YORK.

REGULAR MEETING, APRIL 29, 1915.

DR. J. RAMSAY HUNT, in the Chair.

CASE OF ASCENDING NEURITIS OF THE ULNAR NERVE.

DR. E. G. ZABRISKIE presented from the first division a case of ulnar neuritis in a woman, fifty-six, born in Germany. Occupation, housewife. In September, 1914, she ran a splinter into the outer surface of the left ring finger. Had a slight local infection which healed rapidly, so that in about a week was able to use the hand. From this time on, she noticed a slight numbness in the tip of the finger, but not until February, 1915, did this become very noticeable. At that time it extended to the root of the finger which began to contract and become stiff. This was followed by numbness extending up the arm, and at about the first of March she began to have severe pains in the palm, running up the forearm and into the shoulder. She can move the arm in all directions and there is no limitation of the movements of the elbow joints, but extension of the forearm causes pain in the elbow. She can close the fingers with great effort only.

Examination shows a pale, flabby woman with slight general emaciation. General examination is normal. There is aortic dullness to the right of the sternum and the first aortic sound is loud and rough. Examination of the right hand shows the fingers in a typical position of ulnar palsy. There is distinct tenderness all along the track of the ulnar nerve from the point where it passes over the medial condyle down to the wrist. The muscles supplied by the ulnar nerve are tender on pressure; there is distinct weakness of the interossei. There are no gross disturbances of cutaneous or deep sensibility. Pupils are equal and respond normally. Urine normal.

The interesting features of this condition lie first in the etiological factor; the most reasonable supposition is that we are dealing with a local infection of the terminal filaments of the ulnar nerve, with a subsequent ascending ulnar neuritis, but it is difficult to explain the lapse of time between the healing of the infection and the onset of the neuritis. But, because of the lack of other etiological factors, we are forced to accept this.

A CASE OF FROEHLICH'S SYNDROME WITH BLINDNESS AND CHOKED DISCS.

DR. JUNIUS W. STEPHENSON presented from the second division, a boy, twelve years of age, who two years previously began to have headaches. These headaches persisted, often being so severe as to keep him from school. There was also occasional vomiting, and during the past four months this has been rather frequent and severe. Eight weeks ago vision became affected and this progressed rapidly, until within six weeks there remained only a slight perception of light.

The patient was sent to the Institute by Dr. Dana, April 19, 1915, with immediate history as above stated. The history antedating his illness was uneventful except that he was considered a

"very large" baby and grew proportionately. Measles was the only infectious disease. The mother is a very large woman, weighing three hundred pounds. The father is said to have been "very large"; cause of his death not ascertained. He has one brother who is of large build.

The patient is very intelligent, and states that since the blindness, the headaches though persistent, are not so severe. He often refers to seeing "visions." His stature is large and somewhat flabby. The breasts are quite well developed and of the feminine type. The body hair is very scant. The testicles are undescended. The skin is dry and rough. He weighs 131 pounds.

The superficial and deep reflexes are all present, showing no abnormality other than at times a suspicious extensor plantar response on the right. Cranial nerves normal. The pupils are round, regular, widely dilated and yield only a slight response to light. Dr. Holden reports: Nystagmus to right and also quite marked when looking forward, when light is thrown into eye. Perception of light only. The disc shows papilledema with atrophy; elevation about five diopters.

The blood pressure has ranged between 110 and 120. Pulse 92-106. Temperature normal.

The serological examination of blood and spinal fluid was negative. W.B.C., 5200. Differential: neutrophils, 64; eosinophils, 2; large lymphocytes, 8; small lymphocytes, 25; transitional 1. Repeated urinalyses negative. The sugar tolerance was 500 gms. levulose.

An x-ray of the sella turcica was taken while a patient at the Flower Hospital, and the Roentgenologist has kindly reported the following: "Hypophyseal growth with erosion of sella."

Remarks. The general appearance of the patient, sugar tolerance and x-ray findings leave little doubt as to the location of the lesion causing the symptom complex. The one unusual finding is the presence of choked disc. This might be construed as evidence that we are dealing with a pineal growth and not a hypophyseal. However, we cannot say the patient has not at one time had a hemianopsia, and a pineal growth as large as the x-ray shows this to be (about the size of a hen's egg) would quite probably show some cranial nerve involvement, such as the fifth, and symptoms referable to the third ventricle. Nor would a pineal growth produce the physical stature or influence the sugar tolerance. After the conference it was decided to have performed a puncture of the corpus callosum, and right subtemporal decompression as palliative measures, while awaiting the influence of organotherapy.

April 7th, 1915: Operation by Dr. Elsberg. Puncture of the corpus callosum and right subtemporal decompression. Considerable fluid escaped under great pressure following decompression.

The headaches were considerably relieved. There has been no vomiting. Vision has not been influenced.

May 10th, 1915: Fundi show elevation of one diopter and post neuritic atrophy of the optic nerves.

The case is interesting because of features not usually encountered in hypophyseal growths with their consequent pituitary manifestations. The x-ray demonstrates a hypophyseal growth and the picture presented by the patient himself is distinctly pituitary, but instead of a primary optic atrophy (the usual phenomenon) we find an enormous choked disc. The evidence of increased intracranial

pressure is further corroborated by the operation, which demonstrated the ventricular fluid under great pressure and there was considerable bulging at the site of the subtemporal decompression.

Again the general picture of the patient—small stature, excess of adipose tissue, infantile genitalia, femininity, etc.—presents the clinical picture of Froehlich's syndrome, the unusual feature being that here instead of a primary optic atrophy our patient is developing a secondary atrophy as the result of the general increase in intracranial pressure. The natural assumption is that the tumor is growing upwards in the region of the third ventricle.

A CASE OF UNILATERAL ASCENDING SPINAL PARALYSIS;
REMARKS ON THE UNILATERAL TYPES OF SYSTEM
DISEASE.

DR. J. RAMSAY HUNT presented from the second division, a man, 28 years of age, single, occupation, clerk. His family history was negative and there was no history of antecedent disease or injury which might have a bearing on the affection from which he was suffering. He denied lues and is moderate in the use of alcohol.

Onset: Seven years ago, with weakness and stiffness of the left foot, which gradually progressed and ascended the left lower extremity. During a period of five years these symptoms were limited to the left leg and gradually growing worse. At the expiration of this time, the movements of the left hand also became weak and stiff, and gradually extended to the whole of the left upper extremity.

These symptoms developed in the most gradual and insidious manner, without pains or paraesthesiae. There had been no headache, vertigo, diplopia, or visual disturbances. The sexual power was diminished. The speech is unaffected. Of late, the right leg tires readily on exertion, but there is no stiffness and the patient regards the right side of the body as normal, and refers all his troubles to the left side—the leg being more affected than the arm.

Physical Examination: The man is well developed, stands in a hemiplegic attitude and walks with a markedly hemiplegic gait, dragging the spastic lower extremity with difficulty. The cranial nerves are normal. Pupils equal and react normally. There is no nystagmus, no weakness of the face or deviation of the tongue. Speech is normal. The optic nerves and visual field are normal. The spine shows a well marked scoliosis, compensatory in character. All movements of the spine are free and there is no pain or rigidity. There is a well-marked spastic paralysis of the left leg and left arm. The knee jerks are exaggerated on both sides, left greater than right. The ankle jerks are also greatly exaggerated, the left greater than the right. The arm jerks are exaggerated on the left side. The abdominal reflexes are present and diminished, the left less than the right. Cremasterics present and inactive, left less than right. The Babinski reflex is present on both sides. There is also ankle clonus on both sides. All sensations, both superficial and deep, are entirely normal. There are no evidences of local muscular atrophy or of fibrillary twitchings. Both legs measure the same below the knees, viz., 13 $\frac{3}{4}$ inches. The circumference of the right thigh measures 19 inches and that of the left 17 inches. This difference is due to a slight secondary atrophy of the left thigh (spasticity) and also to a compensatory hypertrophy of the muscles

of the right thigh, this compensatory hypertrophy being the result of the extra exertion required in swinging and dragging the paralysed and spastic left lower extremity. There is no oedema of the extremities and the pulsation of the pedal arteries is normal.

The urine is normal and the Wassermann test of the blood and cerebro-spinal fluid is negative. The spinal fluid contains no increase of cells or of globulin.

The clinical picture is limited to a spastic paralysis of the left leg and arm, of gradual development, which for several years had been limited to the lower extremity. The reflexes on the right side (ankle clonus and the Babinski phenomenon) also indicate a pyramidal tract affection, but without disturbance of the gross motor power or spasticity.

Remarks: This case was presented as an example of that rare clinical type, a *unilateral progressive ascending hemiplegia*, due to progressive degeneration of one pyramidal tract, and first described by Dr. Charles K. Mills of Philadelphia.

It is a lateral sclerosis of unilateral type, the chief interest of which is the diagnostic problem presented, together with the fact that a system disease, which in most cases is symmetrical and bilateral, may on occasion appear and for many years progress as a unilateral affection. Unless the possibility of such an occurrence is considered, it may give rise to considerable diagnostic uncertainty. While in this case the clinical picture is one of gradually ascending hemiplegia of seven years' duration, the pyramidal system on the opposite side also shows signs of beginning degeneration, viz., fatigue of the lower extremity on exertion; ankle clonus and the Babinski reflex, and there can be little question that as the disease progresses, the involvement of the opposite side will become more and more apparent.

In a case described by Mills and Spiller, with autopsy and histological examination, the course of the disease was for many years a progressive hemiplegia, but later the lower extremity of the opposite side became involved (Triplegia). Histological study showed an old unilateral degeneration of the pyramidal system, with more recent degenerative changes on the opposite side.

Some years ago a young woman under my care developed a progressive ascending hemiplegia and later a triplegia; for about five years the symptoms were limited to an affection of the pyramidal tract system. At the expiration of this time the muscles of the hands began to atrophy, and the case gradually merged into the clinical picture of amyotrophic lateral sclerosis. This case is of interest as showing that amyotrophic lateral sclerosis may also begin as a unilateral pyramidal tract disease (ascending hemiplegia) and similar cases have been reported by other observers.

In the earlier stages of the unilateral progressive hemiplegia, a tumor of the cord might be closely simulated, but the absence of pain and sensory disturbances should serve in most cases to eliminate this doubt.

It is of interest to recall a case recorded by Oppenheim of unilateral progressive ascending hemiplegia associated with homolateral sensory disturbances. In this case, Oppenheim made the diagnosis of combined system disease of unilateral type, so that the possibility of unilateral postero-lateral sclerosis as well as one sided lateral sclerosis must be borne in mind.

Not only is the unilateral progressive hemiplegia a symptom-complex of system disease, but it may also occur as an expression of multiple sclerosis, as in a case recorded by Potts. I have also observed, progressive ascending hemiplegia with homolateral slight sensory disturbances, very closely resembling the cases described by Oppenheim as unilateral postero-lateral sclerosis. Later, however, an autopsy revealed old lesions of multiple sclerosis in the spinal cord.

Of very special interest is the occasional occurrence of paralysis agitans as an ascending hemiplegia. The rigid form of Parkinson's disease without tremor is well-known and requires no special comment, but that this may occasionally assume a progressive hemiplegic form is not so well known, and has been emphasized by Patrick of Chicago. In such cases the motor disturbances assume the characteristic rigidity of Parkinson's disease and not the spasticity of pyramidal tract affections.

To summarize then: the unilateral ascending progressive hemiplegia is the unilateral expression of a system disease, such as lateral sclerosis, amyotrophic lateral sclerosis and postero-lateral sclerosis. It may also occur in the earlier stage of paralysis agitans, and like most other clinical types, may occasionally result from an unusual combination of the lesions of multiple sclerosis, and of cerebro-spinal syphilis.

CASE OF ATYPICAL PARALYSIS AGITANS, WITH LIMITED OCULAR MOVEMENTS.

Dr. THADDEUS H. AMES presented from the third division, a man, aged 62, with slowness of gait, a general rigidity of body and speech disturbance.

For about twenty months the patient has been suffering from a progressive loss of "cunning of the hand," and all of his movements have been slower and more awkward. He cannot bend over nor get up from a chair easily, and his gait has been slower. His head is stooped, his eyes staring, and his body rigid, so that as he walks in the street he is an object of attention. He has stuttered all his life, but in the past ten years the stuttering disappeared. For the last year the speech has been slow, monotonous and drawling. No pains, tremors and no trouble in swallowing. Never loss of consciousness. No sphincter trouble. Patient has been extremely constipated during the past twenty months. Previously he was regular.

Examination: Man of weight about 200 pounds. Stands in a stooped position, with head set, shoulders rounded. He walks in a stiff, awkward, slow manner. No festination. No tremors. No ataxia, nor incoordination of hands or feet; no cog-wheel motion of arms. No rigidity of joints. Paralysis of superior recti: right equals left. Slight nystagmus.

Vision: 20/40 in right eye. 20/100 in left eye. Fundi normal. Fields normal. Pupils equal, regular, round. Reaction slightly sluggish.

Speech: Slow, monotonous, drawling. No disturbance in the pronunciation of syllables. No trouble in swallowing. Hearing normal. Reflexes: K. J.'s present and equal. Achilles jerk present and equal. No Babinski. No Oppenheim. Blood pressure 150. Blood Wassermann negative.

Treatment: Patient has been given successively potassium iodide, thyroid gland, pituitary gland, parathyroid and cathartics, without any improvement.

NOTE (Two months later). The condition of the patient is progressively worse. The gait is slower and walking is more difficult. The body is held in even a more rigid position as he walks and stands. When he sits down he has more difficulty than before. He says that he has fallen to the ground a number of times in the past month because his thighs have become so weak, they could not support his body. He does not trip and fall.

The movement of the eyeballs is just the same. There is no rigidity of the arms or legs on rapid passive oscillations. At times, as he makes gestures, there is a momentary coarse tremor of the right hand, but this subsides at rest. This is not an intention tremor.

This case is presented as an atypical form of paralysis agitans, based on the stooped, rigid attitude with slowness of movements, the mask-like countenance and the character of the speech. There is, however, no typical tremor. The most puzzling feature of the case is the presence of the limitation of ocular movements. There is no movement whatever upward or downward of the eyeballs, though the lateral movements are normal. The eyelid movements are normal.

Book Reviews.

What Every Mother Should Know About Her Infants and Young Children. By CHARLES GILMORE KERLEY, M.D., Professor of Diseases of Children, N. Y., Polyclinic Medical School and Hospital. New York: Paul B. Hoeber. 1915.

This little book of about fifty pages "was prepared at the suggestion of a child's welfare organization. Its purpose is to place in the hands of the mother of moderate means, concise, readily understood and practical instructions for the care of her infants and young children." The advice given is, as is all the advice given by Dr. Kerley, reasonable, practical and easily understood. It should prove useful to those for whom it is intended. An unusual feature of the book is that the left hand page is left blank for notes.

The Starvation Treatment of Diabetes. With a Series of Graduated Diets as Used at the Massachusetts General Hospital. By LEWIS WEBB HILL, M.D., and RENA S. ECKMAN (dietitian), with an Introduction by RICHARD C. CABOT, M.D. Boston, Mass.: W. M. Leonard. 1915.

Any practitioner following the suggestions of this book will have greater success in the treatment of his diabetic patients than hitherto. Of course it would have been helpful if the number of cases which had been treated at the Massachusetts General Hospital under the observation of the writers had been mentioned and the results given. However, as it is, the book will be useful because it states in simple form the diets which may be followed by the patient.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THE ORIGIN OF THREE DUBLIN HOSPITALS.

DUBLIN has long been famous for its hospitals, which are not only numerous, but, in many instances, of ancient foundation and, in one case at least, of international repute. There are ten general clinical hospitals in Dublin, with three lying-in hospitals, two hospitals for children, another for contagious diseases, an orthopedic hospital, an ophthalmic hospital, a dental hospital and several other special institutions. Of all these the Steevens' Hospital is the oldest, but the most famous is, of course, the Rotunda.

The Rotunda Hospital had its origin in the sympathetic and far-sighted energy of Dr. Bartholomew Mosse, who was born in 1712 in County Down, the son of an Irish clergyman. Making his resolution to study medicine, Bartholomew was apprenticed to Mr. John Stone, a surgeon of Dublin. Completing this apprenticeship in 1773, Mosse determined to enter the army and, after examination by Surgeon-general

John Nichols, who pronounced him a physician well qualified to practice the art of surgery, Mosse was given medical charge of troops in various British garrisons. In 1738 he went with a contingent to Minorea. Here he seems to have withdrawn from the army service, and after traveling for a time on the continent, he returned to Dublin, and in 1742 was admitted a licentiate of the Irish College of Physicians. By this time he had become particularly interested in obstetrics, an art then far more highly advanced on the continent than in Britain, and he realized the utter inadequacy of the care that could be given to the poor women of Dublin in their homes. He, therefore, undertook to raise the necessary funds to establish such an institution, and finally on March 15, 1745, first opened "an hospital for poor women in George's Lane." This first building of what afterwards became the Rotunda Hospital was a three-storied house, which, with an outbuilding, afforded accommodation for twenty patients.

The difficulty which now confronted Mosse, a difficulty which still constitutes the chief problem of most charitable institutions, was that of obtaining adequate means to maintain the hospital thus established. After the first interest of the public had worn off, sufficient funds could not be raised by mere private subscriptions, and Mosse showed great ingenuity in supplementing these by lotteries, theatricals, concerts, dances and other entertainments. He succeeded so well in fact, and his hospital immediately proved of such value to the community, that he was encouraged to plan a much larger and more ambitious building. The story of this new building, as told by Dr. Kirkpatrick in his admirable history* (reviewed in the issue of the *Lancet* for Feb. 14, 1914), is in part as follows:

"In August, 1748, he took upon himself the responsibility of a lease for three generations of four acres and one rood of land on the north side of Great Britain street, whereon to erect a lying-in hospital for at least 150 patients. He first laid out the grounds as public gardens, after the model of the Vauxhall Gardens, London, upon which he expended some £2000 of his own money, walling in the grounds, erecting an orchestra, concert room, and coffee room, and planting trees and shrubs. Here he organized a series of entertainments with a view to producing a yearly income for the benefit of his char-

*The Book of the Rotunda Hospital. An illustrated history of the Dublin Lying-in Hospital, from its foundation in 1745 to the present time. By T. Percy C. Kirkpatrick, M.D., M.R.I.A., Fellow and Registrar of the Royal College of Physicians of Ireland. Edited by Henry Jellett, M.D., F.R.C.P.I., Master of the Hospital. London: Adlard and Company. 1913.

ity. His expectations were not disappointed, and in fact to this day the hospital still draws a considerable income from the entertainment rooms and pleasure grounds established by him.

"The foundation-stone of the new hospital was laid on July 9, 1751. In December, 1756, a Royal Charter was granted. Mosse was appointed Master for life, and shortly afterwards a parliamentary grant of £6000 was paid over to the governors, less £180 deducted at the treasury in certain imposts.

"Nearly a year later a committee of the Irish House of Commons gave a further grant of £6000 for the completion of the hospital, and a benefaction of £2000 to 'Bartholomew Mosse, Master of the said Hospital, as a reward for his great Care and Diligence in Attending the Lying-in Hospital in *George's-Lane*, thirteen years, and superintending the new Hospital in *Great Britain-Street* nine years and a half, by which he hath greatly injured himself in his profession, and hurt his Family in their Circumstances, having never received any reward.' Thus, after the overcoming of stupendous difficulties the New Hospital, from designs by the great contemporary architect, Richard Castle, was opened on Dec. 8th, 1757, 12½ years after the establishment, as a private venture, of the original hospital in *George's-Lane*. At the time of the transfer from the old to the new hospital Mosse was able to report that 3975 women had been delivered in the old hospital, with a maternal mortality of 1.10 per cent, 'mostly of fever several days after they were safely delivered,' at a total cost of £3913 13s 0¾d."

Unhappily Dr. Mosse did not live long to enjoy the fruition of his labors and to carry out his plans in the administration of the new institution. He died on February 16, 1759, and was succeeded as Master by Dr. Sir Fielding Ould. In his estimate of Mosse's character, Dr. Kirkpatrick says:—

"We find no trace of self-seeking in any of the work done by Mosse. His hospital was everything, and though he claimed honour as its founder, it was only through it and its success that he made any such claim. There is no evidence that he ever used the hospital for his own advantage, either in the way of making money by it, or to advance his professional reputation. Indeed, for the hospital he seems to have sacrificed his entire income and to have abandoned any hope of rising to professional eminence. But little evidence is forthcoming as to his private life, but such as there is seems to proclaim him a good husband and father and a generous friend."

It is evident that Dr. Mosse was a man of unusual personality, of energy, persistence and a genuinely charitable disposition, and the hospital which he established, later acquiring the

name of the Rotunda, has retained to this day the stamp of the individuality of its founder.

Older than the Rotunda hospital, in fact the oldest in Dublin, though not nearly so well known, is the Steevens' Hospital at Kingsbridge in the west end, an institution founded by Dr. Richard Steevens and his twin sister Grizell, children of the Reverend John Steevens, an enthusiastic Scottish Jacobite exiled to Ireland by the iron hand of Cromwell. Born in Athlone, Richard Steevens, after studying divinity for a time, abandoned it for medicine and, removing to Dublin, developed an extensive practice among the poor of that city. There were then no free dispensaries in Dublin, no charitable organizations except the churches, and not a single hospital. The need of medical relief and care was urgent. For years Dr. Steevens and his sister, neither of whom was ever married, devoted their labors and their private fortune to such ministrations as could be carried out in the homes of the poor. It was the doctor's dream to establish a hospital similar to those in the large cities of the continent, but he died in 1712 at the height of his popularity and activity as a medical practitioner without carrying his plan into execution. His sister Grizell, however, on the day following his death, made over to a board of trustees the estate bequeathed to her by her brother reserving for herself only an income of £150 a year. With this fund, the trustees purchased a suitable site near the southern bank of the river Liffey in the poorer quarter of the city and began to accumulate the necessary money for a building. In this there was considerable delay, but finally, in 1720, the first hospital ward in Dublin was begun. It was not completed, however, until 1733. By this time all the members of the original board of trustees had died and had been successively replaced by others, among whom may be noted the distinguished name of Jonathan Swift, then Dean of St. Patrick's Cathedral, whose signature may still be seen in the records of trustees' meetings and in other archives of the hospital. The faithful Miss Grizell Steevens resided at the hospital and acted as its superintendent until her death in 1746 at the age of 93 years. In her time the capacity of the hospital was 40 beds, but it has since been enlarged to over 200. The original building, however, remains as the centre of the present institution, and in it are treasured the portraits of Dr. Steevens and his sister, the documents and other relics pertaining to the hospital's history,

and the living memory of the two faithful and devoted founders who, after years of self-sacrifice and endurance, established for the suffering poor of Dublin their first institution of charitable medical relief.

Neither so old nor so famous as the Steevens' Hospital or the Rotunda, Sir Patrick Dun's Hospital is one of the older and more notable hospitals of the city. Sir Patrick Dun, for whom it was named, was a native of Aberdeen. He was an army surgeon and was present at the battle of the Boyne where he is said to have treated the Prince of Orange for some slight injury. Subsequently Sir Patrick did not return to Great Britain but settled in Dublin, where he became a noted local practitioner and acquired considerable estates in County Waterford.

On his death in 1714, he left his property to the Irish College of Physicians to establish a library and to endow a professorship of medicine. For a century his estate grew rapidly in value so that in 1800 the accumulated income was sufficiently large to establish a hospital in Dublin which was named in honor of Sir Patrick. It was opened for patients in 1808 and enlarged to its present size in 1814. Since this time, however, the value of the Dun estate has steadily dwindled and the hospital has become dependent like others on public charity. In June, 1914, was observed the bicentennial anniversary of the death of Sir Patrick Dun and the centennial of the completion of his hospital; and at this time a considerable sum of the money was raised to constitute the nucleus of a new endowment fund. The hospital has always been closely associated with Trinity College Medical School and the majority of its staff are professors in that institution. Besides caring for the sick poor, therefore, this hospital has had a conspicuous part in medical education in Ireland. It now accommodates about 100 patients. There has recently been opened in the hospital a new ward to be used exclusively for wounded soldiers and sailors, the funds for which have been given by the County Wicklow Red Cross Society. Thus in its present, as well as in its past, Sir Patrick Dun's Hospital has maintained the military association appropriate to an institution deriving its name and origin from a distinguished army surgeon.

These three hospitals of Dublin, unlike the larger and more modern institutions of many cities, have thus a personality and distinction dependent on the circumstances of their origin.

They were not built and fully equipped at their outset with adequate funds derived from taxation or from large charitable gifts; but were conceived in the hearts of men and women who earnestly and sincerely desired to help their poor and suffering fellow citizens. They were dreamed of and worked for, suffered for, earned and brought to full development and usefulness only after years of effort and uncertainty. They are living institutions whose character represents the personalities and lives of those to whom their origin is due.

THE RELATION OF ENTAMOEBA TO MENTAL DISEASE.

It is now well-known that the condition of the teeth plays a not inconsiderable rôle in the genesis of gastro-intestinal disorders, and has an intimate relationship to general bodily conditions. The teeth as a focus for chronic infection are now given their just recognition. Much has been written on this subject in the past few years. It is not, therefore, surprising that the rôle of chronic focal infection, with the teeth as the atria, in the production of psychoses should be investigated and critically scrutinized.

We know only too well that many mental cases have poor teeth and inflamed, suppurating gums. So pronounced and so constant is this in many patients that it is logical to suspect that in some instances there may be a relationship other than coincidence or coëxistence between the mental state and the mouth condition.

With these ideas in mind, an investigation was recently undertaken by Sawyer and was reported to a meeting of alienists and neurologist held under the auspices of the Chicago Medical Society last July (see the official bulletin of the Chicago Medical Society for September 18, 1915). Thirty-five patients were examined, of whom 26, or 74.2% showed entamoeba, while 9, or 25.7% did not show entamoeba. There was a motley group of conditions found in these patients, but 50% were of the manic-depressive type. The general tendency in most cases was to depression. The treatment consisted, in all patients but one, of four hypodermic injections of emetin, one half a grain each day, plus general treatment consisting of hydrotherapy, massage, full meals, outdoor exercise, and other forms of medication. The author asserts that those patients who received emetin treatment in addition

to the general measures instituted responded more rapidly to these general measures after emetin treatment had been given than similar patients not treated by emetin.

His experience in this research leads Sawyer to draw certain interesting conclusions. Briefly enumerated they may be given as follows: Entamoebae are very common in mental disease. Entamoebae generally accompany poor teeth. It may be said that they are practically always present with suppurating gums. They seem to accompany depressed mental states in particular. Constipation is usually caused by these entamoebae, which may accompany other nervous lesions, such, for example, as multiple neuritis. It must be appreciated that mere removal of the entamoeba does not in itself cure the diseased condition, its function being limited to the cure or removal of the cause. In mental cases exhibiting depression, with poor teeth and suppurating gums associated, entamoeba should be sought, and if discovered, the emetin treatment should be administered, to be followed by general upbuilding therapy.

These findings by Sawyer are interesting, and whether or not entamoebae really have any direct relationship to certain cases of mental alienation, it certainly must be granted that decayed teeth and suppurating gums, with the bad oral hygiene necessarily resulting, do not add to the patient's physical health. In fact they may destroy the appetite, lead to gastro-intestinal upset, constipation or diarrhea, salivation, and foul breath, and make of the mouth, gums and teeth excellent culture media and breeding places for the germs there existing, with the possibility of chronic focal infection playing a definite rôle in relationship to anemia, lowered general bodily health, focal toxic or infective conditions elsewhere in the body, and perhaps even to the mental condition of the patient. The condition should surely receive more consideration than psychiatrists have been in the habit of giving it in the past, and oral hygiene should be a by-word among the mentally disturbed as well as it is among the mentally balanced.

articles on "Birth Control" by Mr. Havelock Ellis in *Physical Culture*. In the October number of this publication Mr. Ellis presents the second of his series, in which he discusses more particularly the prevalence of contraceptive methods, the justification of their use, and the responsibility of physicians with regard to their explanation and recommendation. He calls attention particularly to their adoption in the various European countries and in the United States.

"It was in France, so often at the head of an advance in civilization, that birth control first became firmly established, and that the extravagantly high birth-rate of earlier times began to fall; this happened early in the nineteenth century, whether or not it was mainly due to voluntary control. In England the movement came later, and the steady decline in the English birth-rate which is still proceeding, began in 1877. . . If we examine the latest statistics for Europe (usually those for 1913) we find that every country, without exception, with a progressive and educated population, and a fairly high state of social well-being, presents a birth-rate below 30 per 1,000. We also find that every country in Europe in which the mass of the people are primitive, ignorant, or in a socially unsatisfactory condition (even although the governing classes may be progressive or ambitious), shows a birth-rate above 30 per 1,000. France, Great Britain, Belgium, Holland, the Scandinavian countries and Switzerland are in the first group. Russia, Austro-Hungary, Italy, Spain and the Balkan countries are in the second group. The German Empire was formerly in this second group but now comes within the first group, and has carried on the movement so energetically that the birth-rate of Berlin is already below that of London, and that at the present rate of decline the birth-rate of the German Empire will before long sink to that of France. Outside Europe, in the United States just as much as in Australia and New Zealand, the same great progressive movement is proceeding with equal activity."

Mr. Ellis thus puts himself in the position of approving, even enthusiastically advocating, the practise whose phenomenal result probably constitutes one of the greatest perils and weaknesses of the nations in which it prevails. In the present European war, for whose purposes Germany essentially still belongs in the second group, the ultimate decision may well rest on the factor of numbers, on the exhaustibility or inexhaustibility of the supply of fighting men. There is no question that Germany had already begun to feel the deteriorating effects of civili-

BIRTH CONTROL AND DYNAMIC EVOLUTION.

In the issue of the JOURNAL for Sept. 23 we commented editorially on the first of a series of

zation in the decline of her birth-rate. It is well known that this decline has caused the gravest apprehension among German physicians and sociologists, that articles pointing out its danger have appeared in German medical journals, and that measures to combat it have been suggested and even, to a certain extent, adopted.

This attitude of the German medical profession (an attitude largely shared by the French and English, it should be noted) is quite different from that which Mr. Ellis would adopt.

"In Holland nurses are medically trained in a practical knowledge of contraceptive methods, and are thus enabled to enlighten the women of the community. This is an admirable plan. Considering that the use of contraceptive measures is now almost universal, it is astonishing that there are yet so many so-called 'civilized' countries in which this method of enlightenment is not everywhere adopted. Until it is adopted, and a necessary knowledge of the most fundamental facts of the sexual life brought into every home, the physician must be regarded as the proper adviser. It is true that until recently he was generally in these matters a blind leader of the blind. Nowadays it is beginning to be recognized that the physician has no more serious and responsible duty than that of giving help in the difficult path of the sexual life. Very frequently, indeed, even yet, he has not risen to a sense of his responsibilities in this matter. It is well to remember, however, that a physician who is unable or unwilling to give frank and sound advice in this most important department of life, is unlikely to be reliable in any other department. If he is not up to date here he is probably not up to date anywhere."

Mr. Ellis's statements in these last few sentences may be thoroughly sound, but probably hardly in the sense which he intends. That the physician should be a purveyor of the popular knowledge of contraceptive methods seems a prostitution and perversion of his special function to preserve rather than prevent life.

In conjunction with Mr. Ellis's theories may be noted also those of Mr. Casper L. Redfield, of Chicago, upon whose writings we have commented editorially in several previous issues of the JOURNAL. The burden of his contention is that human breeding, to attain the best results, should not proceed more rapidly than at the rate of three generations in a century, and that this end may be attained by the postponement of parentage to the fourth decade of life. This process of selecting the optimum period of life for reproduction (a time by no means definitely determined as yet) he terms dynamic evolution,

and he has recently published a book about it, under this title.* Basing his assertions on the phenomena of horse and dog breeding, Mr. Redfield discusses the possibility of transmitting acquired characteristics, and the consequent preferability of procreation after such valuable characteristics have been developed.

Naturally any such method of dynamic evolution involves birth control, so that the conclusions of Mr. Redfield and Mr. Ellis come to much the same. As a matter of fact, it seems that both have again somewhat mistaken effect for cause. It is not the facts of late parentage and birth restriction which are apparently beneficial, but the improved environmental conditions which often, but not invariably or necessarily, attend them. Not late parentage or restriction, not birth control or dynamic evolution, but improvement of environment is perhaps the factor most needful at present in any attempt experimentally to better the human race.

MEDICAL NOTES.

NEW YORK ACADEMY OF MEDICINE.—The Wesley M. Carpenter Lecture for 1915 will be delivered by George W. Crile, M.D., on "The Kinetic Drive—Its Phenomena and Its Control," on Thursday evening, October 7, at the Academy of Medicine, New York City.

ONE HUNDRED THIRTY-NINE LIVES SAVED IN NEW YORK.—According to figures just issued by Commissioner Goldwater, there were 1236 deaths with a rate of 11.11 last week, as compared with 1232 deaths and a rate of 12.36 for the corresponding week of last year. This difference of 1.25 points in the weekly rate is equivalent to a saving of 139 lives. The following diseases showed a decrease: diphtheria, cerebrospinal meningitis, heart disease, Bright's disease, digestive diseases, pulmonary tuberculosis, lobar and broncho-pneumonia. The only noteworthy increase was in the number of deaths from diarrhoeal diseases in children under five. This increase was due to the warm and humid weather that prevailed last week which caused almost an epidemic of gastro-intestinal disturbances amongst young children.

Considered from the viewpoint of age distribution, there was an increase in the number of deaths of infants under one year of age and between one and five. At the other age periods there were fewer deaths than during the corresponding week of last year.

The death rate for the first thirty-nine weeks

* Dynamic Evolution. By Casper L. Redfield. New York and London: G. P. Putnam's Sons, 1915.

of 1915 was 13.43 as compared with a rate of 13.90 for the corresponding period of last year.

AMERICAN ASSOCIATION OF CLINICAL RESEARCH.

—The seventh annual meeting of the American Association of Clinical Research was held at the Hahnemann Medical College, Philadelphia, from September 23 to 25. The presidential address was delivered by Dr. Jefferson D. Gibson of Denver on the therapeutic use of the x-ray. At the session on September 24, Dr. Thomas B. Crothers of Hartford, Conn., outlined his method of treatment of drug habitués; and Dr. John M. Craig of Philadelphia reported experiments aiming to increase the utility of radium by more economic utilization of its emanations. Dr. Roger M. Griswold of Kensington, Conn., advocated compulsory medical inspection of school children and hygienic improvement of working conditions in the various industries.

AMERICAN ELECTRO-THERAPEUTIC ASSOCIATION.

—At the recent meeting of the American Electro-Therapeutic Association, the following officers were elected for the ensuing year: President, Dr. Jefferson D. Gibson, Denver, Colo.; vice presidents, Dr. J. Willard Travell, 27 East 11th St., New York; Dr. Frank B. Granger, 591 Beacon St., Boston, Mass.; Dr. William L. Clark, 1809 Chestnut St., Philadelphia, Pa.; Dr. Sidney A. Twineh, 24 Fulton St., Newark, N. J.; Dr. William Martin, Atlantic, N. J.; treasurer, Dr. Emil Heuel, 151 West 87th St., New York, N. Y.; secretary, Dr. Byron Sprague Price, 65 Central Park West, New York, N. Y.; registrar, Dr. Frederick M. Law, 576 Fifth Ave., New York, N. Y.

INTERSTATE EXTERMINATION OF MOSQUITOES.

—It is announced from New York on September 28, that Dr. S. S. Goldwater, health commissioner of that state, has established plans to organize an interstate commission for the extermination of mosquitoes. This commission is to have its headquarters in New York City with auxiliary branches in Connecticut and New Jersey. It is planned to secure the cooperation of town, county and state health officials. It is hoped that gradually the work may be extended to other states. Dr. Rupert Blue, surgeon-general of the United States public health service, has offered his approval and aid to the organization.

DECREASE OF TYPHOID IN OREGON.—In 1910, there were in Oregon 172 deaths from typhoid. In 1914 this figure was reduced to 62. While the rate for the country is from 28 to 38 deaths per 100,000 inhabitants that of Oregon for the past year was less than 9.

For comparison it is interesting to note that the typhoid rates for Boston in 1911, 1912 and 1913 were 9.1, 7.9 and 8.2 per 100,000 of population, in the later years about the same as the

whole state of Oregon, and since the rate for Massachusetts is not far from that of Boston, Oregon and Massachusetts are not far apart, with a little advantage in favor of the latter.

INCREASE OF CANCER DEATH RATE.

—Report from Philadelphia on Sept. 22, states that at the annual convention of the Medical Society of Pennsylvania recently held in that city, the cancer commission of the society presented in its report data showing a marked increase in the death rate from cancer disproportionate to the increase in population. Since 1906, the report shows, the death rate from cancer in Pennsylvania has increased 23½%. "Last year the number of deaths from this cause totalled 5197 and the prediction is made that this year the number will reach 6000. The report further states that a large majority of the deaths were unnecessary and could have been avoided if health officials and physicians had been alert in recognizing early symptoms. One of the recommendations made by the commission was that the state examining boards for trained nurses as well as for physicians include among their requirements a thorough knowledge of the early recognition and early treatment of cancer. It was pointed out that the hope for reducing the number of deaths lies not in radical operations in advanced cases but in early treatment."

LOSS OF ST. LOUIS UNIVERSITY EXPOSITION.

—At the beginning of the summer a medical party was sent by the St. Louis University to British Honduras for purposes of research. One member of the party, Dr. Edward Nelson Tobey, was a passenger aboard the fruit steamer *Murawijane* which was wrecked in a hurricane on Friday, Aug. 13, in the Caribbean Sea. He has not been heard from since and is believed to have perished. He was a lecturer in the medical department of the University and assistant bacteriologist of the city of St. Louis.

PREVALENCE OF MALARIA, MENINGITIS, POLIO-MYELITIS AND TYPHOID FEVER.

—The weekly report of the United States Public Health Service for September 17 states that during the week ended August 28, 23 cases of cerebrospinal meningitis were reported in Chicago, 9 cases of poliomyelitis in Cleveland and 90 cases of typhoid fever in New York. During the month of July there were reported in Arkansas 1343 cases of malaria and 138 of typhoid fever.

WORK OF ROCKEFELLER FOUNDATION IN CHINA.

—In last week's issue of the JOURNAL we noted the intention of the Rockefeller Foundation to engage actively in the promotion of medical education in China. In the third part of its annual report issued in New York on September 26, the

Foundation presents the conclusions of its commission which investigated medical conditions in China last year.

"This commission met in Peking about May 1, 1914, and spent the next four months in a thorough study of existing medical schools, hospitals and dispensaries in China, and in conference with missionaries, government officials and other competent advisers in regard to the best means of reinforcing and adding to the important work already done in the field of medical education and public health. A fifth month was devoted to the preparation of an elaborate report of the observations, findings and recommendations of the commission.

"The establishment of the China Medical Board was the result of the commission's report. Dr. Wallace Buttrick, executive secretary of the General Education Board, was appointed director of the board and Roger S. Greene was appointed resident director in China. The president of the Foundation was elected chairman of the board, and Dr. Eben C. Sage, secretary."

SALE OF RED CROSS CHRISTMAS SEALS.—The National Association for the Study and Prevention of Tuberculosis has recently issued a statement of its plans for the sale of Red Cross seals during the coming season; 200,000,000 of these seals are now being printed and prepared for distribution.

"The organization of the Red Cross seal sale this year will take in every state and territory of the United States, including Hawaii, Porto Rico, and the Canal Zone. By Dec. 1 over 500,000 workers,—men, women and children,—will be engaged in the campaign.

"The sale in 1914 broke all previous records, totaling over 55,000,000 seals, an increase of 22% over 1913. After deducting all expenses, this left nearly \$500,000 for tuberculosis work in this country. The money has been and is being expended by over 2000 different agencies who benefited from the sale in amounts ranging from \$100 or less to over \$25,000. The American Red Cross announces that it will continue its previous successful policy of charging only 10% of the gross proceeds to state anti-tuberculosis associations, hereby encouraging local work."

The Massachusetts Anti-Tuberculosis League has been appointed by the National Red Cross as the agent for the sale of Red Cross Christmas seals in that State.

"The League is anxious to have these seals sold in every community in the State, and it is ready to appoint agencies for this purpose.

Such agencies as are properly organized for local tuberculosis work will have the privilege of using 82½% of the proceeds from the sale of the seals in their locality. The League is also anxious to have clubs and other organizations, stores, etc., sell the seals with the understanding that the entire proceeds are to be returned to the League. Bear in mind that the proceeds from

the sale of these seals are used for tuberculosis work in this state.

Applications for these agencies should be sent to the office of the League, 4 Joy Street, Boston, at an early date.

Last year 1,827,982 seals were sold in this State, and the League wishes, through the co-operation of agencies and individuals, largely to increase the sale this year."

EUROPEAN WAR NOTES.

CHOLERA IN GERMANY.—It is reported that during the week ended August 21, there were three cases and one death of Asiatic cholera at Brandenburg, Germany, and 126 cases with 70 deaths among prisoners of war at various detention camps in that country. During the week ended August 28, there were two cases of cholera among civilians at Frankfurt and several among prisoners of war. Nevertheless, the cholera season has nearly passed without a serious outbreak of the disease in Germany and Austria.

DETENTION OF AN AMERICAN SURGEON.—It was reported in New York on September 24 that Dr. Hermann Fischer of the German hospital in that city, who sailed thence on September 9 aboard the steamer *Oscar II* for Copenhagen in company with three other surgeons and four nurses, forming the first contingent of the American physicians' expedition committee bound for hospital service in Germany, has been detained by the British authorities at Kirkwall, England, for lack of the necessary identification papers. It is expected that he will be released as soon as these have been forwarded from America.

GERMAN COURTESY TO AMERICAN RED CROSS UNITS.—Report from Berlin by way of London on September 23 states that the German government has bestowed medals upon all members of the American Red Cross units which have been serving in the hospitals at Gleivitz and Kozel. Similar decorations have been bestowed by the Austro-Hungarian government upon members of the American Red Cross units serving at Vienna and Budapest. At the closure of these hospitals on October 1 nearly all the members of the American units volunteered for service on the German mission to Russia to care for German prisoners in that country and in Siberia. This expedition has already left Berlin, and prior to its departure the members were given a reception by the German crown princess.

WORK OF THE AMERICAN AMBULANCE HOSPITAL.—In the issue of the *Survey* for September 18 was published a communication from the Paris Committee of the American Ambulance Hospital at Neuilly containing a statement by Dr. J. William White, summarizing the work of the Hospital since September, 1914:—

"July 18, 1915.

"At the beginning of this month the records since September last showed that there had been 109,537 hospital days. The expenses per patient per day had been reduced from \$2 to \$1.16. The number of patients had risen from 161 to 535. The ambulance (transportation) service is divided into sections. The Paris section transported during the month of May 932 wounded, at a cost of 1829.90 francs, or 1.96 francs (a little less than 40 cents) a head, a figure which I learn is the lowest yet attained in Paris.

"The total number of cases transported during the month by the various sections, including those at Dunkirk, Pont-a-Mousson, St. Maurice and Juilly, was 10,505, and the average cost per wounded man was 1.79 francs (35 cents). May was the eighth month of effective ambulance service for the hospital and up to that time they had transported 38,057 wounded.

"... I want merely to record my conviction, in fact my definite knowledge, that it (the hospital) has been run most intelligently and with that sense of a proper proportion between necessary and unnecessary economies, and of the difference between extravagance and wise liberality, which marks capable hospital management."

SUPPRESSION OF TYPHUS EPIDEMIC IN SERBIA.
—Report from Naples by way of Paris on September 22 states that Dr. Richard P. Strong, chief of the American Sanitary Commission in Serbia, was about to sail from that port for the United States. In a statement issued prior to his departure he described the situation in Serbia:—

"The situation in Serbia when the American commission arrived was grave, owing to the widespread scope of the epidemic having caused demoralization, and the lack of doctors, whose numbers had been depleted because of the war and disease. There were a few English, French, and Russian doctors working individually, but no central organization existed.

"The Americans remedied this condition, however, by appointing a central commission, headed by Crown Prince Alexander, which was given control of sanitary measures throughout the country. Having full powers, the American doctors enforced the methods that had already borne fruit in the Philippines, in Panama and elsewhere. The whole of Serbia was divided into fourteen sanitary districts, seven of which were intrusted to Americans. One of the most efficacious measures was the disinfection of the population by means of a special train carrying baths, an immense disinfectant for clothing, and cars fitted up as dressing rooms and for shaving and hair-cutting.

"By this train system hundreds of persons would have their clothing disinfected and washed in a few minutes. Thousands were reached daily in this manner, the train proceeding from station to station as fast as the

work could be done, the houses in each place visited being disinfected at the same time. All those found affected with typhus were taken to hospitals.

"The entire Serbian army and numbers of the people have been vaccinated against cholera and typhus, the vaccine being manufactured for the most part in the American Red Cross laboratory. By August last virtually all the epidemics that had been raging in the country were suppressed, and the spread of typhus in Montenegro had been prevented by adopting energetic sanitary measures."

It is expected that the majority of American physicians who have been engaged in Red Cross work in Serbia will leave that country on October 10.

RELIEF WORK OF ROCKEFELLER COMMISSION.—The second part of the annual report of the Rockefeller Foundation issued in New York on September 25, describes the work of the Rockefeller War Relief Commission in Europe from August 14, 1914, to January 1, 1915:—

"The commission expended for Belgian relief \$1,185,146.46 and later received refunds for expenses of ships and for the cargo of the steamer *Massapequa* from the commission for relief in Belgium, \$199,107.52, making the net amount expended by the Foundation in this phase of its work, \$986,038.94. This sum purchased more than 27,000,000 pounds of flour, more than 2,000,000 pounds of rice, 2,000,000 pounds of bacon and large amounts of coffee, lard, salt, sugar, milk and new and old clothing. In addition to purchasing food, the Foundation acted for several months as the receiver for clothing for Belgium, establishing a temporary office in New York for that purpose.

"Within two weeks after the outbreak of the war the Foundation appropriated money to enable Dr. Alexis Carrel, of the Rockefeller Institute and attached to the French army medical corps, to purchase anti-meningitis serum and anti-dysentery serum as well as setting aside funds for the use of the American Red Cross in sending physicians and nurses to Europe.

"In addition to its work for the Belgians, the Foundation sent a commission of three to Europe to inquire into relief measures needed in all the countries affected by the war. This commission was composed of Wickliffe Rose, director-general of the International Health Commission; Ernest P. Bicknell, National Director of the American Red Cross; and Henry James, Jr., manager of the Rockefeller Institute for Medical Research. They visited Belgium and Holland and made a survey of the organizations for relief in those countries. The commissioners later went to Poland and Serbia and by January 1 their recommendations as to relief measures by the Foundation had been presented to the trustees for consideration.

"Another feature of the Foundation's work was an appropriation at the rate of \$20,000 a

year for those professors of scientific subjects in the University of Louvain who had been obliged to abandon their laboratories and who had been provided with opportunities of pursuing their labors in England."

WAR RELIEF FUNDS.—On Oct. 2 the totals of the principal New England relief funds for the European War reached the following amounts:

French Fund	\$17,534.18
Italian Fund	8,114.57
Red Cross Fund	1,481.61

BOSTON AND NEW ENGLAND.

WATER SUPPLY OF FALL RIVER.—The conservation of the water supply of Fall River has at last become necessary and measures are to be taken to prevent the pollution of the reservoir upon which the city is dependent for its water. Watuppa Pond, once the largest pond in the state, is now divided into two parts and the south pond has been taken for manufacturing purposes; the various mills on its banks rendering it unfit for drinking purposes. The north pond, therefore constitutes the only source of water in the peninsula in which the city is situated. The growth of population has approached the pond so closely that its pollution is imminent. To prevent this the number of brooks and streams feeding the pond will be diverted into the south pond and the forestry zone will be well protected. That the preservation of this reservoir can be accomplished is said to be easily possible at this time, although as early as 1875 the likelihood of city growth into the watershed to the injury of the water supply was discussed and the project of an intercepting drain was broached.

REGULATION FOR FOOD WRAPPERS.—Dr. F. X. Mahoney, health commissioner of Boston, has recently issued a notice to storekeepers, directing that newspapers may not be used for the purpose of wrapping any article of food. This regulation represents an interpretation of the statute which prohibits the use of unclean paper for the wrapping of food stuffs.

HOSPITAL BEQUESTS.—The will of the late Isaac H. Eddy of Dorchester, Mass., which was filed on September 22 in the Suffolk Probate Court contains a bequest of \$10,000 to the Massachusetts Homeopathic Hospital and \$5,000 each to the Home for Incurables, the Boston Floating Hospital and the Industrial School for Crippled and Deformed Children.

The will of the late Dr. George Haseltine of Haverhill, Mass., who died recently in New Jersey, contains a bequest of \$5,000 to the Hale Hospital at Haverhill.

REGISTRATION OF BIRTHS.—The department of health of the city of Boston has recently issued the following circular letter to every member of the profession in this city:—

"Your attention is called to the following:
'An Act Relative to Reports and Records of Births.'

(Acts of 1912, Chapter 280.)

"Section 1. Physicians and midwives shall within forty-eight hours after the birth of every child in cases of which they were in charge, mail or deliver to the clerk or the registrar of the city or town in which the birth occurred a notice stating the date and place of birth, giving the street number, if any, the number of the ward in a city and the family name. Failure to mail or deliver the said notice shall be punished by a fine not exceeding twenty-five dollars for each offense."

"The reason for calling your attention to this law is that you may have all births which you have attended to date reported to the City Registrar of Boston, as after October 1, 1915, if any birth is found not reported in accordance with the above statute, the physician in charge will be prosecuted."

"Respectfully yours,

"FRANCIS N. MAHONEY, *Health Com.*
"E. W. MCGLENEN, *City Registrar.*"

Obituary.

AUSTIN FLINT, M.D.

DR. AUSTIN FLINT, the distinguished New York alienist, physiologist and consultant, who died in that city of cerebral hemorrhage on September 22, 1915, was born on March 28, 1836, in Northampton, Mass., the son of the distinguished physician of the same name. After being for a time in Harvard College he withdrew to undertake the study of engineering, but soon turned his attention to medicine and in 1854 attended the medical school of the University of Louisville. Later he went to the Jefferson Medical College at Philadelphia, from which he received the degree of M.D. in 1857. Upon his graduation he presented an address on "The Phenomena of Capillary Circulation," which early showed his ability as a physician and a writer.

For several years Dr. Flint practiced his profession at Buffalo, where he became editor of the *Buffalo Medical Journal*, which had been founded by his father. At this time also he received appointments as professor of physiology in Buffalo University and visiting surgeon to the Buffalo General Hospital. In 1859 he removed to New York, where he settled in practice with his father, and was made professor of physiology at the New York Medical College. The following year he was appointed to the same profes-

sonship in the New Orleans School of Medicine. Returning to New York in 1861, Dr. Flint became one of the founders of the Bellevue Hospital Medical College, in which he served as professor of physiology from 1851 to 1898. He was also professor of physiology at the Long Island College Hospital Medical School from 1865 to 1868 and at the Cornell University Medical College from 1898 to 1906.

At the outbreak of the Civil War, Dr. Flint volunteered for service in a surgical capacity and throughout the war served as assistant surgeon U.S.A. at the New York General Hospital. In 1875 the value of this war experience of Dr. Flint was recognized by his appointment as surgeon-general of New York, a position which he held for four years. In 1891 he was decorated with the third class of the Order of Bolivar, Venezuela. He served for varying periods as visiting physician and consulting physician at the Bellevue Hospital and at the Manhattan State Hospital for the Insane.

It was through his lifelong interest in physiology that Dr. Flint was led to his particular studies in psychology and mental diseases. As early as 1863 he conducted experiments on alligators and other animals for the purpose of investigating the functions of the liver, the phenomena of circulation, especially the inhibitory action of the vagus, and the recurrent sensibility of the anterior roots of the spinal nerves. He also studied methods of determining the nitrogenous content of the blood. He was a prolific author on medical subjects, his most notable works being his several text-books on physiology and a monograph on "Source of Muscular Power." He was a member of the American Medical Association, the American Academy of Medicine, the American Philosophical Association, the American Medico-Psychological Association, the Association of Military Surgeons, and of his state, county and local medical societies. His life and work are noteworthy examples of the contributions of a distinguished American medical family. He is survived by his widow, one daughter and three sons, one of whom, his namesake, is also a physician.

JOHN EVANS SHEPARD, M.D.

DR. JOHN EVANS SHEPARD of Brooklyn, N.Y., who died on September 13 at Putnam, Conn., was born of a Quaker family at Woodland Farm, Greenwich, Cumberland County, N. J., in 1859. He graduated from Haverford College in 1879 and in 1882 received the degree of M.D. from the University of Pennsylvania. After serving as interne in the Pennsylvania and University Hospitals of Philadelphia, he began the practice of his profession at Atlantic City, N. J., where he was attending physician at the Mercer Memorial Home and at the Seashore Annex of the Friend's Insane Asylum of Frankford, Pennsylvania. In

1889 he removed to Brooklyn, where he became professor of otology at the New York Polyclinic and at the Long Island College Hospital, consulting aurist at the Brooklyn Hospital, the Jewish Hospital, St. Catherine's Hospital, and the Brooklyn Eye and Ear Hospital, instructor in otology at the New York Postgraduate Hospital and Auricular Surgeon at the Brooklyn Throat Hospital. He was a prolific author of papers in otology and laryngology and was a member of many general and special medical societies. He is survived by his widow and one daughter.

JOHN MERRICK BEMIS, M.D.

DR. JOHN MERRICK BEMIS, who died at Worcester, Mass., on September 22, was born in that city in 1860, the son of a physician. After obtaining his preparatory education at Andover Academy, he graduated from the University of Vermont and obtained the degree of M.D. from that University in 1883. He then became associated with his father, the late Dr. Merrick Bemis, in the administration of the Herbert Hall Hospital of Worcester, where he became noted for his work as a neurologist. He was a Fellow of the Massachusetts Medical Society and a member of the New England Society of Psychiatry and the American Psychological Society.

Miscellany.

THE WELSH NATIONAL SCHOOL OF MEDICINE.

IN the issue of the JOURNAL for August 26 we noted the establishment of a national medical school in conjunction with the University of Wales. The corner stone of the first building of the physiological department of this school was laid at Cardiff on August 12 by Lord Pontypridd. This new Welsh National School of Medicine had its origin in the school of medicine of the University of South Wales and Monmouthshire, which was established in 1893. As early as 1885 at the time of the annual meeting of the British Medical Association at Cardiff in that year, Dr. W. T. Edward, then president of the Association and physician to the Cardiff Infirmary, who had long cherished a desire for the establishment of a Welsh medical school, gave the sum of £1,000 for the foundation of such a school. In 1893 a further sum of £7,000 was raised for alterations and extensions of the original buildings of the school at Cardiff, and in 1894 these extended buildings were opened by Sir Richard Quain, then president of the general medical council. Since his time, instruction has been provided at this school in the subjects of the first three years of medical study, and since 1899 graduate courses have been offered to

wards the degree of doctor of public health. In the issue of the *British Medical Journal* for August 21, 1915, is presented the following further sketch of the history of this Welsh school of medicine and of the new institution by which it is to be extended and replaced.

The first professor of anatomy was Dr. Alfred Hughes, who died during the Boer war after serving in South Africa. His memory is perpetuated in the school by a medal and by a fine anatomical museum. He was succeeded by Professor Dixon, now of Dublin, and the present occupant of the chair is Dr. Hepburn, now in command of the 3rd Western General Hospital at Cardiff. During this time Dr. Berry Haycraft has been continuously professor of physiology. During the twenty-two years 224 former students have obtained medical qualifications and have won 32 gold medals and distinctions at the University of London. They have also won 45 entrance scholarships into London hospitals.

The council of the college has worked in cordial relation with the authorities of King Edward VII Hospital. The professor of pathology and bacteriology of the college is one of the honorary pathologists of the hospital, and is now commanding officer of the mobile bacteriological laboratory of the Welsh Army Corps; and all the work of the school in pathology and bacteriology, which has hitherto necessarily been of a post-graduate character, is done at the hospital, where the necessary rooms and laboratories have been provided by the foresight of the hospital authorities for that purpose. The department was opened by Sir William James Thomas on June 1, 1912.

Since 1909 the college has received a grant from the Treasury for the purposes of the medical school. In 1906 the University of Wales obtained a supplemental charter authorizing it to confer degrees in medicine and surgery, but owing to the want of a complete medical school at Cardiff, students have hitherto had to go to other schools for the later subjects of the medical curriculum. In 1908 Professor Haycraft drew attention to the need for new physiological laboratories, both for teaching and research, and three years later, at the instance of Colonel Bruce Vaughan, chairman of the House Committee of the Cardiff Infirmary, a committee of the council of the college was appointed to consider the needs of the department of physiology and the comparative claims of other departments. This committee recommended that greatly improved accommodation for the medical school was required. Eventually, in February, 1913, Sir William James Thomas offered a sum of over £10,000 towards the cost of building the new department of physiology, and in the end undertook to erect the whole of the buildings required for physiology and to increase his donation to £30,000 so that the great hall and staircase for the use of the complete school

of medicine should be provided at the same time. In January, 1914, Sir William James Thomas announced that he was prepared to promise a further sum of £60,000 to provide a public health department and school of preventive medicine, together with the necessary buildings for a complete school. One of the conditions attached to the offer was that the Treasury, in addition to its present annual grant of £1,500, should make a grant adequate for the administration and maintenance of a school worthy of Wales. In February, 1914, a deputation consisting of members of the University of Wales and its constituent colleges and of other bodies interested in medical education in Wales, appealed to the then Chancellor of the Exchequer, Mr. Lloyd George, for government assistance towards the maintenance of a complete medical school for Wales at Cardiff. Mr. Lloyd George promised a substantial contribution from the Government, and a scheme has recently been submitted to the Treasury by the Welsh Educational Conference for the formation of a University of Wales Council of Medicine. The school will thus become a national institution controlled by a national body, while its administration will, subject to certain conditions, remain in the hands of the Council of the University College of South Wales and Monmouthshire.

The new physiological buildings, with the great hall and staircase, now to be erected, form the first part of the larger scheme for the complete school of medicine. The new building will face onto the Newport Road, one of the principal thoroughfares of the city, and will be within five minutes' walk of the hospital. When completed it will measure 368 ft. from east to west. The physiological department will occupy 116 ft. of its frontage, and the hall, which will be common to all departments of the new school, 42 ft. The design, by Colonel E. M. Bruce Vaughan, F.R.I.B.A., provides a basement, a ground floor, four upper floors, and a mezzanine between the first and second floors. It will have a depth of 47 ft.

The eastern part of the basement and ground floor will be occupied by a large lecture theatre to seat 140 students; adjacent to it will be preparation rooms and a museum. The first floor, to be devoted to experimental physiology, will contain large laboratories for forty-eight students, a smaller laboratory for advanced students, the professor's private room and private laboratory, a dark room, a departmental library, and a workshop. The second floor for chemical physiology will contain a students' laboratory with eight benches for five students each, a lecture room for small classes, a research laboratory, a private room and a research laboratory for the lecturer in chemical physiology and store and preparation rooms. The third floor will be entirely devoted to histology and embryology. The laboratory with both top and side light will provide accommodation for 80

students, and there will also be a lecture room, a demonstration theatre, a room for the lecturer, a laboratory for advanced students, a museum for embryological and histological specimens, and preparation and store rooms. Above the third floor there will be a photographic dark room and an optical room.

"In the design of the front the need for abundance of light has been fully recognized, and the façade shows many windows. The centre and end blocks and the wide bays between are stone. The main walls will be faced with narrow red bricks joined with light mortar. The general design is English Gothic of the fourteenth century, modified by the influence of the French Renaissance architecture of the following century. The central block rises to a height of 100 ft. with side turrets, between which will be a pointed arch deeply recessed. The lower portion of the central feature, forming the portico, will be divided into three bays by columns surmounted by canopied niches to contain the statues of Hippocrates and Aesculapius. The flanking panels will contain busts of Pasteur, Lister, Hunter, and Jenner. Over the central block will be a lantern with a vane rising to a height of 150 ft. above the ground. The entrance hall will measure 65 ft. by 30 ft. and the ceilings will be panelled, showing the arms of each county in the Principality with the arms of Wales in the centre."

A NEW ANTISEPTIC.

IN a recent issue of the JOURNAL we announced the reported discovery by Dr. Carrel and others of the efficacy of a mixture of boric acid and chlorinated lime as an antiseptic in wounds. It is pointed out in the issue of the *Lancet* for August 14 that this is not a new discovery, but a method of applying the already recognized and well known antiseptic properties of hypochlorous acid.

"It is a good many years since we announced from the *Lancet* laboratory that the activity of ordinary bleaching powder was greatly increased by passing through it carbonic acid gas, which liberates hypochlorous acid. Any other acid—e.g., boric acid—will do the same thing. In 1894 we investigated the Hermite process for the sterilization of sewage, which consisted in passing a current of electricity through sea-water, which was demonstrated to produce hypochlorous acid. The germicidal power of this electrolytic fluid was shown to be more than equal to corrosive sublimate; it was found to possess the advantage that it did not become inert by forming insoluble compounds with albumins, while it could be very cheaply produced. We pointed out at the same time that a practically identical fluid, except for an excess of common salt, could be produced by passing carbonic acid gas through a solution of bleaching powder. Later it was found that by adding bicarbonate

of soda in excess to bleaching powder solution a fluid was obtained containing free hypochlorous acid, although the product possessed acid-neutralizing properties due to the excess of bicarbonate of soda present. In all these cases, therefore, the 'new antiseptic' is an old and familiar friend, hypochlorous acid. It is doubtful whether bleaching powder or really neutral calcium hypochlorite has a strong germicidal value. It is not until its hypochlorous acid is set free that it becomes a powerful antiseptic, and in the methods just described certain additions are made to the bleaching powder—e.g., bicarbonate of soda or boric acid—which effect the liberation of this weak and unstable acid. When bicarbonate of soda is used the advantage is gained that all free and corrosive alkali is removed, and yet the mixture possesses acid-neutralizing properties. The bleaching properties of such a mixture are very intense, and this intensity is no doubt on a par with its germicidal power. It is well known that one of the difficulties of using bleaching powder for bleaching purposes is that its caustic properties due to lime are apt to destroy the fabric. When, however, it is employed with an excess of bicarbonate of soda a bland, non-corrosive fluid results which, while equally effective as a bleach, is free from the destructive properties described. 'A new antiseptic' therefore amounts to this: that bleaching powder or sodium hypochlorite has been primarily employed, but that the lime or soda has been neutralized by the addition of boric acid, which would liberate hypochlorous acid, which possesses only a feeble acid character. It can hardly be supposed that the boric acid contributes to the antiseptic value, since it would be present as borate of lime or of soda, as the case may be; its addition merely means the liberation of hypochlorous acid. Most probably the addition of an excess of bicarbonate of soda to bleaching powder solution would give equally gratifying results in the antiseptic treatment of wounds. Some valuable experimental observations on the antiseptic action of hypochlorous acid and its application to wound treatment were recorded in the *British Medical Journal* on July 24. The observations, undertaken at the request of the Medical Research Committee, were made by Professor Lorrain Smith, Professor Murray Drennan, Dr. Theodore Rettie, and Dr. William Campbell, and the result was to confirm the conclusion of various investigators that hypochlorous acid is the most powerful antiseptic known."

CASES OF INFECTIOUS DISEASES reported to the Boston Board of Health for the week ending Sept. 28, 1915, are as follows: Diphtheria, 41, of which 4 were non-resident; scarlatina, 17, of which 4 were non-resident; typhoid fever, 19; measles, 7; tuberculosis 67, of which 3 were non-resident. The death rate of the reported deaths for the week was 14.33.

RELIEF OF DEAFNESS AND APOPLEXY.

BOSTON, Sept. 26, 1915.

Mr. Editor: I have just read your editorial upon Dr. Lawrence and S. Johnson. In writing about the fallacy of "broken ear drums" I found that Sir Wm. Wilde, in 1852, quoted Sir Astley Cooper (1800) as having entirely removed that fallacy! Now, in 1915, it occurs to me to note that very few physicians could correctly diagnose the cases of those of whom you have written. And even if these few could do so their statements would not be credited. However, by reaching the fountain head, it is possible to change the river's course and I venture to show you a modern method of relief from "deafness and apoplexy." In all cases of continued progressive deafness it is usual to find evidences of the effects of disease in childhood. These are opacities or scars in the m. t. These always hint at a "chronic retropharyngitis" with hypertrophied Luschka's tonsil.

Although in a few cases where hypertrophy continues late in life the patient may carry around all the germs that "flesh is heir to" upon the sticky mucus of that region, as these cannot penetrate the surface under ordinary conditions health continues. In most patients, sooner or later, the coccus of rheumatism begins developing and a slow toxinization ensues to produce from time to time the "endarteritis deformans," or the "sclerosis which precedes the apoplexies," or sometimes it is "thrombosis," at other times "embolism," and sometimes "rupture of sclerosed artery." With the local infecting processes are found all the complications which produce the "old man's bronchitis," the "clergyman's sore throat," the symptoms becoming local or reflex, or both, according to the varying character of the lesions.

In so-called heart asthma one often finds this due to an inhibitory reflex through the nose; specifically, irritation by swelling in the region of the sphenopalatine ganglia. This interesting symptom occurs during many of the normal nasal reflex phenomena, sneezing, coughing, hicough, etc. Recall what takes place when one's nose is covered by another's hand! A struggle immediately occurs to remove the inhibiting object. Imagine what an obstructed nose can do to induce the various phenomena or symptoms of asthma. In this connection I remember what part the so-called respiratory centre plays in these.

It is, perhaps, needless to write of the treatment because it would not be possible to carry this out in the very aged to the extent required by the local conditions. It is, however, easy to attempt sterilization of the nasopharynx by passing through the nose cotton-tipped probes dipped in hydrogen peroxide and whenever the kidneys are not seriously affected this should always be advocated.

I am very anxious to have some one carry out this procedure during an apoplectic seizure—either immediately or during convalescence, for if fluid can be absorbed from inflamed knee-joints in a few hours, as both Dr. Bryant and I have seen, after a sterilization of the nasopharynx, why should not similar processes take place elsewhere, as in the brain?

Very truly yours,

EDWARD D. SPEAR, M.D.

VALUE OF QUININE AS AN ANTISEPTIC.

BROOKLYN, N. Y., Sept. 22, 1915.

Mr. Editor: In the N. Y. Daily Times of Sept. 22, 1915, there appeared an article indicating the value of quinine as an Antiseptic and Cure of Gas Gangrene, the most infections, rapid and fatal of diseases.

I wish simply to say that for the last 15 or 20 years past I have used quinine as an antiseptic in all labor cases in my practice and have not lost a single case. I have given it a week before confinement and after, until I leave the case, a 3-gr. quinine pill three times

a day, and have proven it the best antiseptic in my practice. Yours very respectfully,

MARSHALL L. BROWN, M.D.

331 East 23d Street.

ANALYSIS OF 308 CASES OF TYPHOID FEVER IN CHILDREN, WITH STATISTICAL LITERATURE.*

By K. G. PERCY, M.D., BOSTON.

[From the Medical Department of the Children's Hospital of Boston.]

I WISH to present the analysis of 308 cases of typhoid fever which have been treated in the Children's Hospital of Boston since 1913. This series embraces children from infancy through the twelfth year. Two cases of thirteen are included as twelve, for both had been surgical or orthopedic cases, which showed signs of typhoid soon after their admission or operation.

In compiling these statistics I have procured my percentages from the total number of records which mentioned the point desired and will not bother you continually in giving each time the number of cases in each series.

Age incidence shows statistically 5 cases, or 1.6%, under 2 years; 95, cases, or 31.6%, between 2-5 years; 200 cases, or 66%, between 6-12 years. In the literature of 4717 cases (9, 2, 6, 10, 3, 8, 11) there are 2.2% under two years, 27.8% between 2-5 years, 66% between 6-12 years.

Seasonal Occurrence is but a matter of textbook interest and my statistics show that 51%

were admitted during the months of August, September and October; 11% more were admitted in November. This coincides with 76% given by Adams¹ for July, August, September and October. Yet the appearance of local epidemics in April and May in two years raised their frequency during these months to 13%.

The Type of Onset was noted but seldom, though in general the younger the child, the more sudden the onset, definite sickness occurring over night or during the day. The older children give an indefinite history of malaise for one to seven days before chilliness, fever, headache, epistaxis or diarrhea occurred. Blackader² gives onset as sudden in 13%. Griffith,³ in infants, gives onset as sudden in 35%, rapid in 27%, gradual in 37%.

The Duration of Sickness before Entrance was noted in 268 cases, showing 35.4% under 1 week, 46.2% 1-2 weeks, 13% 2-3 weeks, 2.7% 3-4 weeks, 2.9% over 4 weeks. In other words, 82% of all cases were so sick that the parents felt that their children needed hospital care or the local doctor had made a tentative or positive diagnosis of typhoid before the children had been sick for 2 weeks.

Fever was noted in the histories in 82% of this series. This, I believe, is incorrect observation of parents or negligence of the admitting physician, for Walker⁴ gives 100%, Hand and Gillings 100%, of history of fever. Yet on admission 100% of this series had fever.

Headache was a marked symptom in 57%, and in the children over 4 years old it was noted in 69%. In the literature of 1210 cases (11, 2, 6, 9, 9, 8), headache is noted in 66%.

* Read before a meeting of the New England Pediatric Association on February 24, 1915.

The Spleen showed enlargement to palpation on entrance in 68% of cases and was noted as enlarged to palpation in 79% of all cases some time during their stay in the hospital. The figures given in the literature of 1356 cases (9, 2, 6, 7, 11, 1) show enlargement of the spleen in 70%.

Rose Spots were noted 94 times in 280 careful records, or 33%, at entrance and a total of 57% some time during the course of the disease. Recurrent crops appeared with relapses or even recrudescence of fever, and have the same significance in children, after the temperature curve has once struck normal, as in adult practice. Of the cases reported in the literature, I find their frequency put at 61% in 2372 cases (9, 2, 6, 7, 11, 1, 5).

Widal's Tests were done on 280 of this series. If positive once, that was sufficient. If negative, they were repeated one to four times, until positive or other evidence found for diagnosis.

80 % were positive on admission.
13.2% more were positive during their stay.
7.8% were negative.

Outside of this list I have five positive to one of the paratyphoid reactions, thus 93.2% of all typhoid cases in this series gave a positive Widal reaction during their course, and this laboratory work was done in our own laboratory, in the City Board of Health Laboratory and at the Harvard Medical School. In the literature I find 88% of 447 cases gave positive Widal's.

Let me here review the cases with negative Widal's,—16 in all. Of these

- 3 gave history of typhoid in family and ran a typical course.
- 4 had both rose spots and spleens and ran a typical course.
- 4 had enlarged spleens and ran a typical course.
- 1 had rose spots and ran a typical course.

The last 4 I have questioned as real typhoid cases.

- 2 had splenic enlargement and ran a fever less than 3 weeks.
- 1 had questionable rose spots and ran fever for 2 weeks.
- 1 had typhoidal history but ran fever for 10 days only.

Probably these 4 would have shown positive paratyphoid agglutinations had they been tried. Of the *Paratyphoid* cases there were five proven by the agglutination reaction.

Spleens were noted in 2 or 40%
Rose spots were noted in 1 or 20%
No complications.

An average duration of fever of 16 days and
An average stay in the Hospital of 25 days.

White Blood Cell Count was done in 258 cases at or within 3 days of admission.

14% were below 5,000
57% were between 5-10,000
29% were between 10-15,000.
Though 25.6% were in the 10,000 count.

Hand and Gillings⁶ in 111 cases note that

81% were under 5,000
64% between 5 and 10,000; and
27.7% between 11 and 15,000.

Griffith, in 75 infants, reports that the white count was not over 10,000 in 84% of his series.

In the *Urinary Examinations* I have simply collected, as a matter of interest, statistics in 76 cases where Diazo reactions were done. Fifty-one cases, or 67%, either at entrance or within the first 10 days, were positive. The figures of Adams and Walker (1, 9) in 182 cases show that they found the Diazo reaction positive in 24.8%.

Blood Cultures were done in 17 cases only of this series. Twelve cases, or 70%, were positive. Of the five negatives, three were taken on the 10th day and the Widal on that day was positive; one taken on the 4th day with a coincident positive Widal, and one taken on the 11th day with a coincident positive Widal. Of course this series is too small for correct deductions, but these results are to me quite surprising.

Bowels Activity. During the hospital course 299 cases showed:

Constipation in	52 % of all cases
Diarrhea in	16.7% of all cases
Normal activity in	37 % of all cases

Walker⁹ reports in his 71 cases,

42% showed constipation.
38% showed diarrhea.

Relapses occurred in 60 cases of 300 records where the patients stayed in the hospital until discharged well, or in 18% of this series. Five cases had two relapses. The literature of 1002 cases (9, 11, 2, 5, 1) shows relapses in 10% of cases. Thirteen of the relapses in our series were coincident with increase in diet, 3 with giving of cathartics (A. S.+B. pills or castor oil), 2 probably with getting up too soon, and the rest were unaccounted for.

17 %	occurred between the 10-20th day of sickness	(This seems questionable.)
49.2%	occurred between the 20-30th day of sickness	
17 %	" " " 30-40th " " "	
13 %	" " " 40-50th " " "	
3 %	" " " 50-60th " " "	

Of 59 of these where the duration was noted,

18.6% lasted 7 days or less.
10.2% lasted 7-10 days.
25 % lasted 10-15 days.
30.4% lasted 10-20 days, and
16 % lasted over 20 days, with an average of 13 days.

Griffith noted relapses in 15 infants of his 75, with a duration ranging from 5-19 days.

Hemorrhages of the intestines occurred in 4 cases, one of whom died and another of whom had as its apparent etiology a severe purpura with hematuria. Thus this series shows that hemorrhages occurred in 1.3% of all typhoid cases. In the literature I find 4.4% of hemorrhages in 4691 cases (9, 6, 7, 5, 3, 11, 8, 1), as against Holt's¹² figures of 3% in 946 cases. The hemorrhages in this series are all noticeable on

the chart by rise in pulse and temperature, and in three cases with a rise in respiration. They were all noted clinically at or soon after their onset, before the appearance of tarry or bloody stools and were treated by starvation, morphine and cold locally to the bowel in 3 cases.

Perforation of the bowel does not enter our series, though the literature of 2788 cases (4, 6, 7, 11, 8, 1, 13) shows an incidence of 1.8%, as against Holt's¹² figures of 1.1% in 1028 cases.

Complications were noted in 102 cases, or one-third of this series. In this series I have included otitis media, which appeared 51 times. Of those having otitis, 78% were 4 years or under, and justly this cannot be classed as a typical typhoidal complication in our knowledge of its frequency in debilitated children in hospital wards. Thus without otitis we have complications in 51 cases, or 16% of this series. Yet, further, I had included bronchitis as a complication. It surely is to me a more serious complication than otitis and often seems to have a very definite relation to typhoid, yet without this complication and otitis, our percentage of cases having complications fall to 9%. G. Andreoli¹⁵ in the *Thèse de Paris*, 1913, No. 430, gives the percentage of complications in 1295 cases as 10.6%. Of our series 50% had otitis (and only 1 mastoid), 24% had bronchitis, 13% boils or superficial skin infections, 5% meningismus, 3% pneumonia, 3% parotitis, 3% abscesses, 2% jaundice, nephritis, purpura and osteomyelitis, 1% intestinal hemorrhages and pyelitis, and single cases with phlebitis, meningitis, cholecystitis, empyema (not typhoidal), psychosis, deafness, noma and colitis.

On the question of *typhoidal insanity* in childhood, I wish to quote D. L. Edsall's¹⁴ statistics of the literature of 89 cases, where 63 recovered, 33 remained insane, though 43 died during the course of typhoid.

The average length of stay in the hospital for 300 cases that remained until convalescence or death was 5 1/3 weeks, or in other figures, 73% left before the 42nd day.

Mortality. This series shows a mortality of 2.9% in 306 cases. (Two cases which were discharged against advice are excluded.) In other words, 9 died.

1. 10 years old on 36th day from toxemia and in relapse.
2. 13 years old on 46th day from toxemia and sepsis following a surgical operation previous to first symptom of typhoid.
3. 5 years old on 23d day from int. hemorrhage and noma with coincident measles.
4. 6 years old on 7th day from toxemia (dying 12 hours after entering hospital).
5. 3 years old on 6th day from toxemia.
6. 7 years old on 30th day from toxemia following mastoid infection.
7. 4 years old on 35th day from otitis media and meningitis.
8. 1 year old on 39th day from pneumonia, otitis and enterocolitis.
9. 2 years old on 22d day from otitis and broncho-pneumonia.

Of the 9 cases, 7 gave history and ward record of diarrhea, 5 gave history of relapse, 2 gave history of infection through other members in their family. In the literature of 6732 cases (9, 4, 2, 6, 15, 8, 11, 7, 1, 16, 17, 18, 19, 20, 21) the mortality is given as 5.5%, against Holt's figures in 2603 cases of 5.4%. I have not included in my list the earlier statistics of Heborn, Guinain, Brennan and Torias, given in *Pediatrics*, New York, 1907, Vol. xix, p. 530, as 14%, 17%, 17% and 12%, respectively; nor have I included Griffith's mortality in 75 infants as 16%.

On treatment, my statistics have but little to offer. This series began, luckily, after the time that antipyretics were in vogue, and I find no note of this type of therapy, save the giving of sodium salicylate in a case complicated by arthritic pain and tonsillitis. Intestinal antiseptics were not tried either. Urotropin was occasionally used on various services toward the end of convalescence in hopes of discharging the cases with urine free of typhoid bacilli, yet in two cases where this was done and sterile cultures of urine planted, both cases showed positive cultures 3 and 5 days before discharge. Hydrotherapy has been almost universally used for temperatures over 103.5° F. A good number of histories have no treatment noted and but rarely have the results of this therapeutic measure been commented on in the after notes, save in cases where the "child did not tolerate the cold pack," or "fretted over each administration of cold sponge" or the note is made that "the sponge seemed to quiet the delirium." The routine is to give sponges at temperature of 85° F. for temperature 103.5 or over. Despite this negative evidence, I am personally convinced that hydrotherapy has a very definite power for good, not only as a sedative, but as a vascular and cardiac tonic, though, as in all therapy, it should be carefully adapted to the individual patient.

Medicinal Therapy divides itself into stimulants, sedatives, and symptomatic use of drugs. *Stimulants* for vascular inefficiency were used in 41% of all cases, though I did not mention in my complications cardiac weakness as shown by signs of myocarditis; its frequency is far greater than I have been led to believe by perusal of the literature. A rapid, thready, poor tension or irregular pulse is of common occurrence in the long protracted fevers or in cases of marked inanition. To my mind this frequency can be greatly diminished by a higher caloric diet, but when present, it has been well combated by the use of strychnia, in the early days by brandy, and occasionally by digitalis preparations and caffeine. *Sedatives* were used but rarely in delirium and occasionally to tide over a case in extreme pain from some complication. *Symptomatic Drugs* which were utilized, comprise antiseptics for skin and month infections, those for bronchitis and occasionally for diarrhea.

Cathartics, I believe, have no place in the medicamentarium of typhoid therapy. In three instances, of the very few noted in this series,

relapses began on the day of or the day following their administration.

Enemata, on the other hand, are an essential, harmless and most efficient means of therapy in this disease in childhood.

Autogenous or *stock vaccines* were used in 5 cases with no marked beneficial results, and in 2 of long protracted febrile state their use was followed by complications in both instances. This series is too short to be of value, but the results of vaccine treatment were far from startling, and to me the scientific principle is wrong.

Leucocytic Sera were used in three cases with no apparent beneficial effect on the temperature curve, the course of the disease, relapses or complications, as two out of these three had either a relapse or a complication. Again I give these meagre statistics as a matter of interest only.

Lastly, I wish to mention diet. Here again statistics are of little help unless the individual daily food charts are available for each patient. Luckily such were available in many instances. Our early statistics show the administration of "liquid diet" in the early, or throughout the febrile phase of the disease. I have tried to make note of the result of an increase in dietary upon the clinical charts. In 171 cases noted, as beginning on liquid or milk diet, 68 showed a rise in temperature on the day of or within two days of the addition of "soft solids." These rises in temperature were never over 101°. They had some slight coincident rise in pulse that lasted from 4 to 12 days, or an average of 6.3 days. This series omits 13 cases which I have previously made mention of as true relapses. Furthermore, it has been the custom in the last few years to give every patient a fuller dietary from the start, and I can find no increase in frequency of relapses, but do find an actual decrease in the duration of the disease, both as to the febrile state and the total length of stay in the hospital. Typhoid children can be made to take a relatively high calorie diet, bland, non-irritating and not tiresome, and I am convinced that it is a great essential for the success of the treatment.

IN CONCLUSION.

Typhoid is a relatively common disease in childhood and far more prevalent in infancy than formerly supposed.

Symptomatically it is ushered in very much as in adults, with headaches, fever, malaise and abdominal pain as the most frequent symptoms.

In this series and in a large collected series from the literature.

The spleen is enlarged in 71% of all cases.

Rose spots are seen in 61%.

Positive Widal's are seen relatively early in 88.2%.

White blood count is below 10,000 in 73%.

The fever lasts an average of 25 days.

Relapses occur in 11.8%, intestinal hemorrhages in 4.2%, perforation of intestines in

1.2%, complications in 10.6%, and the mortality is 5.3%.

Therapeutically. A diet, bland, high calorie, and suited to the individual need of each patient, is most important.

Hydrotherapy seems to have a vital place in the treatment of the febrile and delirious stage of the disease.

Enemata are essential in a high percentage of cases.

Stimulants and other symptomatic drugs are to be used as need arises, for typhoid is a disease, cured not by medicine, but by good nursing and keen, sensible therapy; for, as Dr. Morse has said, "the tendency in all these cases is to get well, no matter what the treatment, unless it is absolutely bad."

THE THERAPEUTIC VALUE OF OCCUPATION FOR THE INSANE.

By EMILY L. HAINES, BOSTON.

Supervisor of Industries for the Massachusetts State Board of Insanity.

I.

For some years past much has been said about the therapeutic value of occupation and diversion for the insane. However, in reports of a great number of insane hospitals, fifty and seventy-five years ago, the same idea was expressed as at the present time and the various occupations were mentioned.

In the report of the Trustees of the Worcester State Lunatic Hospital, dated Dec. 30, 1835, we find the following:—

"Experience has proved the vast importance of labor and its utility. There are in the hospital more than a dozen able-bodied men who can labor daily in the field, and as many others that may be employed a part of the time profitably and pleasantly. An institution of this

kind will have a large number of working men among its inmates at all times. We find these always inclined to labor. Shut up in halls, or in their cells, they are unhappy, restless, discontented and in consequence less mild and docile, often troublesome.

"Another beneficial influence of labor which operates alike on the sane and insane mind, and which greatly enhances its utility, is the idea of production for benefit. This idea of practical utility, this witnessing the results of their own labor in the improvements of the grounds and walks, in the culture of flowers, the growth of vegetation, the manufacture of tools and implements, and such comforts as contribute to the benefit of those who are within the reach of their influence,—all these and similar pursuits lead the mind from the consideration of causes to their effects."

The city of Boston established a hospital for her insane at South Boston in 1839. This was the third hospital in the state, the first being the McLean Hospital, in 1818; the second, the Worcester State Hospital, founded in 1833. The Boston City Hospital was placed between the Workhouse and the House of Correction. When it was completed the insane were taken from the penal institutions, where many had been kept in strong wooden cages on wheels. In fine weather, as an extraordinary touch of kind treatment, these cages were drawn out of doors. When the hospital was ready it was a simple matter to transfer the insane in their cages to the new building, where they were at once released and treated like human beings.

Dickens, in his "American Notes," in describing his visit to the Boston City Hospital in 1842, speaks of the patients as working, reading, playing at skittles and other games, and said, "In the garden and on the farm, they work with spades, rakes and hoes. For amusement they walk, run, fish, paint, read, and ride out. They also have a weekly ball."

The Taunton State Hospital was opened in 1854. In the report of that year the Superintendent, Dr. George C. S. Choate, has written as follows:—

"In traversing the halls of lunatic hospitals, even those where no expense has been spared in any department, every person must be struck with one great want which stares him in the face at all points. I mean the lack of occupation.

"At least two-thirds of the inmates of lunatic hospitals are capable of some employment and need it as much as sane people, or more. And yet, even in institutions where the greatest pains have been taken to introduce new amusements, and everything which can make the time pass agreeably and profitably, a large portion of it is spent by most of the inmates in sheer apathy and idleness.

"In acute cases, after the excitement has passed away, I believe that employment of some sort is more important than it is in any other

situation in which a man can be placed. The great object of treatment in such cases must obviously be to divert the attention from self, from the subjects of delusion, and fix it, without exercising it too severely, on some other interesting object. This can in no way be so effectually done as by interesting the patient in some occupation.

"In melancholy cases, what so likely to be beneficial in calling the mind away from gloomy meditations? And in all how necessary is employment to induce sleep, which is so frequently disturbed in insanity, and to promote the health of all the animal functions, which is so important to health of mind."

In this first year 30% of the men and 17% of the women are noted as employed.

From report of 1867 of the Northampton State Lunatic Hospital:—

"Man was made for occupation and activity. They are essential to his well being, both bodily and mental. What is true of mankind in general, in this respect, is true of the insane. Occupation, either bodily or mental, is desirable for all whose health will admit of it; and the occupation should, as far as practicable, be such as will contribute to health by sufficient corporeal exercise. This is especially true in respect to all who have been accustomed to manual labor.

"It may still be asserted, as in some earlier reports, that not less than three-fourths of all the labor upon the premises, within doors and without, is performed by patients. . . The mass of effective laborers are the incurable beneficiaries of the state. But there are many exceptions to this rule, and it not infrequently occurs, in all classes of curable patients, that when the person begins to work we feel a full assurance that he will be restored to mental health; and this assurance is rarely falsified."

Then follows a list of the articles made and repaired (pillows and mattresses). The Superintendent adds: "It is to be regretted that there is not more of this work, so well adapted to the capacity of a large number of patients; could it be increased threefold, that increase would be a great blessing."

In this same report of 1867, under "Exercises and Entertainments," the Superintendent has written: "The plan of having a diversity of exercises and entertainments within doors, which was adopted anterior to the time of the last annual report, has been continued, and not only the actual number, but the proportion of patients partaking in those exercises has been increased."

A list is given showing the number of times in which the patients have assembled in the course of the year, for each of the several exercises or entertainments:—

1. Exercises in the chapel, on the sabbath:
Divine worship in the afternoon. 52 times
2. Exercises in the chapel, on regular evenings:
Scriptural reading and sacred music. 177 times

Poetical reading and sacred music.....	24	times
Prose reading and sacred music.....	24	"
Lectures.....	45	"
3. Exercises in the Rotunda:		
Dance in the evening.....	26	"
4. No gathering.....	17	"
Total days in the year.....		365

The Superintendent has expressed his views on the desirability of Chapel services on Sunday and states that more than two-thirds of the patients of the hospital attended during the year.

The evenings of Scriptural reading and sacred music, the patients met together in the chapel and a chapter from the Bible was read and two hymns were sung, accompanied by the organ. The average attendance for the year was nearly two-thirds of the number in the hospital.

The selections of poetry read included the pathetic and humorous, and the average attendance was 1 and a decimal more than the average attendance of the Scriptural evenings.

In this year of 1867 prose readings were given for the first time, and the report records that the "success was far beyond anticipation." The average number attending these readings was 4 and a decimal more than the number attending the poetical evenings.

The 45 lectures covered a variety of subjects, including: "Description of Dublin," "Oxygen, with Experiments," "The Howlers or Howling Dervishes of Constantinople," "The Reformation," "Structure and Functions of the Liver," "Nature and Causes of Insanity," "Exhibition with the Magic Lantern." The average number attending was 9.12 more than the number attending the prose evenings; this number was only 18 less than the average attendance upon the Sabbath.

Many of the patients considered the six lectures on insanity as the most interesting of the course. To what extent they applied to themselves the knowledge gained, could not be determined, but the doctor suggested that many of them applied much that was said "to their neighbors."

In closing this part of his report he has said, "I believe these exercises to be among the most valuable means for the attainment of the important object for which the hospital was founded."

The library of 1250 books was accessible to the patients on certain days. Magazines, weekly and daily papers were read by the patient.

Under amusements, the bowling alley, billiards, baseball, and swings are mentioned and apparatus for indoor games had been purchased.

The report for the year 1868 is similar to the year 1867, but an increased average in attendance is noted at the entertainments, although 24 days are mentioned when no entertainment took place. Backgammon and battle dore are also mentioned among the games.

Again in 1869 we find the Superintendent writing that five times as much work could be done, such as renovating beds, if they had it.

In this year prose reading numbered 103

times and Scriptural reading 83 times; 16 days are mentioned when there was no assembly.

The report of 1873 states that that year for the first time in the history of the hospital an attendant was regularly employed throughout the year for the special purpose of working out of doors with the patients. In all suitable conditions of weather he was out with from six to twelve men, ready to do anything which appeared necessary or proper to be done. In stormy weather the same company found employment within doors. In this report is stated the following:—

"It has long been considered that one of the principal elements of the superiority of the British, and some of the continental hospitals, over the American institutions of the same kind, is the extent to which manual labor is introduced into them. It is not alone more extensive than here, but it is better organized, and consequently more constant and systematic. At most, if not all, of the county asylums of England, all the clothing, for both men and women, with, perhaps, the exception of hats for the former, is made upon the premises and mostly by patients.

II.

The work of the Hospital is to recover to such whose condition still makes it possible, the use and enjoyment of their bodily and mental functions, and to restore them to their place in life and society. To appease, and to conceal by appeasing, the condition of those who are considered to be outside of recovery.

It is claimed that occupation of some kind is necessary to the contentment and well-being of every individual. To the normal person occupation gives a deep and persistent interest in the varied phases of life, also diversion and pleasure. To many that are sick it can give much the same, while to the mentally sick it is acknowledged to be the most powerful single agent in a curative treatment.

Training and mental occupation exercise a most salutary effect upon the mind and strengthen it against many causes of insanity.

Observation and experience have shown that occupation of the hands leads to the diverting of the mind from itself. That the gradual and progressive training in hand and mind occupation exercises a growing force in the patient's recovery.

As a remedy, occupation brings in a new and outside interest, which may go far toward bringing about a self-forgetfulness, mental and physical. It affords a training in habit, which if well ordered tends toward contentment and confidence. Occupation has a socializing effect upon the patient, lessens restraint, restlessness and insomnia.

Mental enfeebleness of the individual is the result of insanity, and by idleness this enfeebleness is continued or increased. Only by persistent effort, and use of the functions which re-

main to him, is the patient enabled to retain them.

The result of all mental action is an increased power to act, and a tendency to act again in the same way. Development and training mean an increase of the mind's power, and a tendency to act again in a given activity.

The failure to employ the faculties of the mind can cause a low condition of habit, and produce indulgences and vices directly favorable to insanity; while a mind regularly engaged in sound and healthy exercises escapes such demoralizing tendencies. Idleness gives opportunity for introspection. The old adage, "Satan finds some mischief still for idle hands to do," was never more true than in relation to the insane.

Occupation should be adapted to the capabilities of the patient. The work should be stimulating and attractive, and if possible allow the patient an opportunity to express some individuality. If it fails to stimulate, the mind wanders and it is time for some change. Forced attention is not only wearing but ineffectual. Too close attention is tiring and exhausts the nervous energy, thus reducing the power of attention. Work should divert and entertain as well as occupy.

It is often said that no rule can be laid down and that individual cases are treated differently. However, in most cases I believe occupation should be somewhat varied; one form should not be continued too long or long enough to become monotonous and merely mechanical, for then the tendency of the patient is often to drop it. Monotonous or long continued work is known to have a depressing, deadening or irritating effect even upon the mind of the normal person. Hard work, if varied, is less likely to upset and become injurious.

With many of the mentally sick there is little of the power of judgment or reason. But what is taught can be acquired only by the patient using his own activity. So that occupation is desirable which secures from the patient his best mental effort. Successful employment means interest, and the methods must be individual. It is said that the growth of the power of attention may be viewed as a progressive formation of habit. As a general rule, the mind distinctly perceives only those objects to which it gives some degree of attention, the exceptions being those cases in which the mind is spontaneously incited and held by the attractiveness of the object perceived.

"The attractive force of a stimulus is determined not simply by its quantity, but also by its quality—by its agreeable, disagreeable, or indifferent character," also by association.

Unusual or unfamiliar sights and sounds may arouse the attention momentarily, but the quality of being interesting must be present if the attention is to be held. This may depend upon some aspect of the object, as being unusual, possessing beauty of form or color, suggestiveness,

association, or some other attribute; but much depends upon the mental vigor at the time. As we all know, a mind preoccupied is unfavorable to attention, and to arouse it is needed a stimulus of greater force.

These very facts prove that in occupational therapy in a hospital it is necessary to have many forms of occupation; for what may prove an attractive stimulus to one may not necessarily prove so to another.

We are interested in things we understand, or of which we have at least some knowledge. If we know nothing of mechanics we are not likely to be interested in a complicated machine. On the other hand, if we have some knowledge of basketry, weaving, or lace making, the sight of an unusual basket, a beautiful woven scarf, or an exquisite piece of lace immediately arouses our interest and secures our attention. Many people are keen observers in relation to those things which interest them, while they can be quite unconscious of other surroundings. Interest invites and sustains attention. Many times that which is associated with a pleasurable interest or is interesting and new will secure and hold the attention where other attempts have failed. Curiosity may also be a powerful aid. Many times, if the attention is secured, interest is aroused. If this can be repeated then the interest comes more easily, and harder tasks become possible.

Each response of the mind toward the doing of hand work renders it quicker in responding again toward the same kind of stimulus. What is at first difficult and irksome tends to become easy and pleasurable, as practice lends skill and capability. Although a process may be interesting in itself, it would become irksome if the result did not help to sustain the interest.

When an impression is made upon the mind, to become effective it must be again repeated, and over and over. Without practice and repetition the impression gained loses effect after an interval the frequency of the repetition is the determining factor, and not only the number of repetitions. A dementia precox patient may be able to make bobbin lace, but it means the steady application of the teacher and pupil for a period each day until the pattern is mastered. To repeat the lesson with the patient one, two, or three times, and then leave her alone for a week, would probably mean that the process would have to be begun all over again. On the other hand, if these lessons were continued too long at one time, or too often, they might still be unsuccessful.

Occupations vary in their action upon the patients. With some, the employment which brings in color and texture appeals strongly. Others are interested in form, while others are pleased with the problematical side, or a simple mechanical process.

Color yields a great and varied pleasure and is as stimulating to many as music and is necessary and useful. Color in itself tends to depress

or exhilarate. Monotony of color is both depressing and tiring.

In one hospital a girl was weaving toweling. It was the same thing yard after yard, and she seemed to have but little interest in it and frequently left it to wander about the room. The experiment was tried with her of weaving near the ends of each towel a border, using a color. Perhaps one towel would have bands of blue and another of red, the two towels being separated with a line of color. This simple device changed the whole aspect of the work and was successful in keeping the girl interested. With many women the pleasure of weaving lies almost wholly in the use of color.

A dementia precox patient, who was weaving the plain centre of a scarf, was always asking for color. Finally the desire to weave the colored border prevailed, and the scarf was finished several inches shorter than was originally planned. After this experience her next weaving was planned to include lines of color across at intervals of two or three inches.

Suggestion enters life in a hundred forms and ways. It varies with individuals. While some are most sensitive to a suggestion, with others an opposite impulse to the suggestion may be awakened. This is an important factor in the daily life of the insane.

The natural impulse of children to imitate those about them, in all sorts of actions, is seen again in older people. If we notice only, for example, the latest fashion, as seen in dress, dancing, or other amusements, we at once see that grown-up folks are merely older children. The mentally sick are no exception to the rule. The tendency to imitate those about us is a very important aid to development; and this impulse may be of great value in the work of occupation in the hospital.

If the majority of the patients are doing something, the natural impulse (even of many demented patients) is to try to follow the example. On the other hand, if the majority are doing nothing, there will be an atmosphere of unrest, if nothing worse, and there will be little that is conducive to work and healthful condition.

Environment, as with the normal person means much; plenty of space, air and sunshine are necessary for well being. As the report of Dr. Earle said, the effect of music, quiet recreation, social enjoyment, dancing, pictures, games and religious exercises,—each has its place. Play aids industrial, social and moral efficiency. Whatever our vocation, our recreation is that which acts refreshingly upon mind and body and relieves the monotony of that vocation.

The question whether a patient should be given the same kind of work that he or she was accustomed to do in previous life, or should be interested in something quite different and new, is one that no fixed rule can determine. With some patients it is noticed that their interest is awakened by doing something that brings back a memory of their past life and experience.

With others the reviving of familiar work can but revive associations that have a depressing and detrimental effect. Each case, in fact, has to be studied and treated separately, and according to its own conditions, at many times. An English physician has stated as follows in favor of giving a wholly different kind of occupation: "A town-bred artisan, such as a tailor, admitted in a low state of bodily health, if sent out daily for gentle employment in the garden, generally becomes greatly improved physically, and concurrent with the physical improvement, often comes gradual restoration of reason. So also a rustic, inclining to dementia, if put to work at a trade often brightens up considerably, whereas, if sent out to work on the farm or in the garden, employment that he has been used to from birth, would set to work at it mechanically, and it would be of but little benefit to him."

A sense of accomplishment can act as an incentive to the insane as well as to the sane. Work should be graded, going from the simple to the complex. If it is too simple, interest will flag; on the other hand, if it should be so complicated as to be unsuccessful, it may take weeks to undo the depressing effect.

The old time curious, rightly called crazy, things produced should make way for something of real value to the patient, the institution, or the community. Although it is better for a patient to make or be employed on almost anything rather than be empty handed and idle, yet the health-giving value is greatly increased if the work done is something really worth while. It inspires self-respect, induces to further effort and undertaking; and whatever inspires and encourages produces a mental and bodily state of real restorative value to the patient.

The mere fact of giving materials to patients is not enough to produce the desired effect. Some teaching is generally required beside gentle persistency and tact.

The method of teaching should be one's own, and should embody one's own ideals and convictions, and should fit one's individual power. The effectiveness of teaching comes from what one puts into it. Honest praise for effort, result, or both, is worth while wherever it may be. Appreciation is desirable, but a critical attitude is often deadening to all further effort.

While occupation of the patients is of economic value to the institution, lessening the number of attendants needed and the wear and tear upon the attendants, and all concerned, this aspect of the matter should be secondary and kept subordinate to the main purpose—the remedial effect and value of the work upon the patient.

In many cases the knowledge and training gained by occupational work in a hospital has enabled the patient to go back into the world and apply the acquired knowledge and handicraft as a means of livelihood.

To the incurable, occupation appeases the

hopelessness of life and means that each day is made more bearable, and that something akin to happiness is put in place of a dull and colorless existence.

THE TEACHING OF APPLIED THERAPEUTICS AT TUFTS MEDICAL SCHOOL.

By FRANCIS H. McCrudden, S.B., M.D., BOSTON,

Assistant Professor of Applied Therapeutics, Tufts Medical School, Boston; Director of Laboratories, Robert Bent Brigham Hospital, Boston.

THE teaching of therapeutics, one of the most important subjects in the medical curriculum, is one of the weak points in American medical schools. The fundamentals of drug treatment are taught by lectures and laboratory exercises in the department of pharmacology, and the actual details of treatment incidental to the instruction in clinical medicine; but no systematic instruction is usually given in the general principles of therapeutics as an independent subject. During the past year an attempt has been made to strengthen the teaching of therapeutics at Tufts Medical School by giving, in addition to such instruction as is usually given, a course which shall bridge over the gap between pharmacology, physiology, chemistry, and the other fundamental sciences upon which treatment is based, on the one hand, and the actual details of handling patients from day to day, on the other hand; and shall serve as an introduction to the general principles of applied therapeutics. Though the course is still in an embryonic stage, various expressions of interest on the part of the students, colleagues, and others have influenced me to make a statement concerning its purposes, scope, and methods in the hope that such a statement might stimulate helpful criticism.

It is, of course, true that the forms which any one disease may take,—depending on the severity of the disease and on the fact that different patients react so differently to disease with difference in age, sex, constitutional characteristics, and other factors,—show so many different clinical pictures in different patients, and change so much from day to day in any one patient, that the treatment of every new patient is a new problem, and that, therefore, the actual details of treating sick patients can properly be learned only by long continued bedside observation of many patients under treatment, by the inductive experimental methods now used in teaching the subject in the departments of clinical medicine. We treat individuals rather than diseases. And this is especially true in the case of chronic diseases where the exact details of treatment depend largely on the severity of the disease, on the extent to which function is disturbed, on the condition of the patient as a whole, factors concerning which good judgment is gained,—since exact measurements play but a

very small part,—only by long, clinical experience with cases of all grades of severity. But there are, nevertheless, certain general principles relating to the purpose and methods back of the many details which cannot well be taught incidental to the other instruction in clinical medicine and which deserve and need treatment as a separate subject.

Pharmacology deals with some of these principles of treatment but not all, for this is not the province of pharmacology. Pharmacology deals with the action of chemical compounds in the body, with the physiological action of substances quite independently of their therapeutic effect; it deals with the action, not only of those substances which are useful in therapeutics, but also those like muscarin, curarin, and saponin, which are not useful in therapeutics and whose action is chiefly harmful; furthermore, in the case of useful drugs, pharmacology deals not only with those activities which are of therapeutic significance, but also those which are not. Although until very recently this was not strictly true, and pharmacology could hardly be said to exist as a science independent of practical therapeutics, it has now developed to such an extent that it is pursued as an independent science without reference to the practical needs of medicine in the same way, and with the same justification, that chemistry, and physiology,—both of them once a part of practical medicine,—are now pursued as independent sciences. In actual practice, drug treatment is nearly always combined with other forms of treatment: agents such as heat, cold, baths, rest, exercise, posture, diet, massage, electricity, x-rays, high altitude, and sunlight are very extensively used in therapeutics. An intelligent application of these other agents depends upon a knowledge of physiology, physics, chemistry, psychology, and other factors, as well as pharmacology, and the other factors,—even such a one as the personality of the physician,—are, in certain instances, of more importance than the strictly pharmacological knowledge. A knowledge of pathology and clinical medicine, especially, though not necessary for the pharmacologist, is an absolutely necessary pre-requisite for the study of therapeutics; the therapeutically important questions relating to the effect of pathological conditions in altering the action of drugs,—we now have abundant evidence showing that drugs may have a different effect in pathological conditions from what they have in health,—and to when and how to use drugs in disease is outside the province of pharmacology; furthermore, questions relating to diagnosis and prognosis which have to be taken into consideration in therapeutics, and good judgment in estimating the effect of treatment on the clinical condition require a knowledge of clinical medicine. A knowledge of pharmacology alone, then, is not a sufficient basis for the treatment of diseased patients.

There is, therefore, a deficiency in the usual medical curriculum and an urgent need for a

course dealing with the general principles of applied therapeutics, a course which shall bridge over the gap between pharmacology and the other fundamental sciences upon which treatment is based and the actual details of treatment themselves. It is such a course that has been added to the medical curriculum at Tufts. *Since students take up the study of medicine for the purpose of learning to treat sick patients, this course covers the most important department of medicine; the practical purpose of pathology, physiology, diagnosis, and other fundamental branches is to help us treat the patient; the details of therapeutics as demonstrated in the subsequent clinics are shown as illustrations of the practical application of these principles of therapeutics.*

The first question taken up is that of the purpose of treatment. This question, not such a simple one as it may seem at first, and one often lost sight of in actual practice, is very fundamental, since upon the point of view adopted toward it depends the whole character of the course in applied therapeutics. When the surgeon treats a broken bone or removes a diseased appendix he aims at ridding the patient of all evidence of disease, but when the physician uses digitalis, diuretics, and other agents in cases of heart disease his purpose is neither to remove a diseased valve nor to make it whole, but to improve cardiac function. In both cases, however, the aim is,—and this is the fundamental purpose of all treatment,—*to improve the functional efficiency of the patient.* How we go about improving the functional efficiency of a sick person depends upon the nature of the disease, the principles of treatment in acute and chronic diseases, for example, showing certain distinct differences.

The ideal of treatment in acute disease is complete removal of disease, diseased material, or the causes of disease,—the antitoxin treatment of diphtheria, and the removal of a diseased appendix are examples. In treating those acute diseases for which there is as yet no known specific cure the principle of treatment is very simple; in the hope of increasing the resistance of the patient to the disease, we support his strength, promote his comfort, give him in its broadest sense the best hygienic environment possible. It is clear that such methods are aimed not directly, but only very indirectly, at the disease itself; the disease itself is left to run its course under conditions which, so far as our knowledge goes, and so far as we can influence the conditions, we believe to be most favorable for the patient. Though we hope and believe that under such treatment the patient's chances of succumbing are decreased, it is, nevertheless, often questionable how much such methods shorten the course of the disease, or influence it in other ways. The therapeutics of acute disease are, therefore, largely a matter of detail; the general principles of treatment are comparatively simple.

In chronic disease the ideal is somewhat dif-

ferent. When the heart, for example, is so far diseased that the amount of work which it can do is less than the amount of work required of it,—when compensation fails,—the leaky valve or other anatomical change responsible for the condition cannot be removed or made whole. This is not necessary; the patient with heart disease often knows nothing of the anatomical changes responsible for his condition; he wants the symptoms alleviated so that he will be more comfortable and able to do his work. In other words, it is not *anatomical integrity*,—about which he may know nothing,—which interests the patient, but his *functional efficiency*. On account of the very great reserve powers,—the high factor of safety,—of all our organs, an organ may be the seat of disease and yet be functionally efficient; it has been calculated that the normal heart, for example, can do six times the work ordinarily required of it: and we know that the factor of safety of certain double organs, like the lungs and kidneys,—since one of the pair can be entirely removed without danger to the patient,—must be at least one hundred per cent.; but with severe disease, there comes a time when the affected organ cannot perform the amount of work ordinarily required of it, and the physician is called in to restore equilibrium between the work required of the organ and the work which it can do. Two general groups of methods are utilized to restore equilibrium: (1) methods which decrease the work required of the organ, (2) methods which stimulate the power of the organ to do work. We have long recognized that drugs cannot qualitatively change function, but can only increase or decrease function; the same thing is true of other forms of treatment; under their influence, function may be increased or decreased but not qualitatively changed. A knowledge of therapeutics, especially the therapeutics of chronic disease, consists largely of a knowledge of (1) methods of stimulating organs or functions, (2) methods of resting organs or functions, (3) knowledge of when and how to apply such methods. Though the diseased organ may never become normal as the result of treatment, it may, nevertheless, be made functionally efficient, that is, competent to its tasks.

Every opportunity is given the student to observe methods of treating acute disease, but since,—as the considerations which follow will, I think, show,—training in the treatment of chronic disease is the only training that can lay the foundation for a rational knowledge of therapeutics, stress is laid particularly on the principles of treatment of chronic disease. The details of treatment in chronic disease depend on the *severity* of the disease, on the *degree* to which functional efficiency is impaired. Since we have made scarcely a beginning in our methods for the exact measurement of functional efficiency, all estimates of the severity of the impairment of function and of the degree of change, either for better or worse, in the severity

of the disease depend on the judgment of the physician. Judgment concerning the degree of disturbance of a function like circulation, for example, depends on estimates of the severity of the dyspnea, cyanosis, weakness on exertion, and other more subtle changes, none of them capable of very exact measurement, and a comparison of these changes with those seen in many other cases. To this kind of judgment must be added, as the basis for the treatment of each new case, experimental observation of the effect of treatment in influencing the severity of the disease. Such knowledge and judgment is acquired only as the result of long experience combined with proper training and some natural ability and aptitude for this kind of work. In other words, in contrast with the standardized, simple, exact, and easily learned treatment of acute disease, the treatment of chronic disease requires long clinical experience, good training, and special talent in observation and comparison. In acute disease, furthermore, but a small proportion of the population suffers at any one time, and the illness lasts but a short time,—in the course of a few weeks the patient is either well or dead: the most important feature of the treatment belongs to the field of preventive medicine. With chronic disease the case is quite different. A large proportion of persons who have reached middle life suffer from some weakness of function, some handicap based on a physical defect,—in its widest sense, some form of chronic disease,—this is not over in a few weeks; the patients may live a long time and must adjust themselves to their handicapped condition. In such cases it is the province of the physician to help them adjust themselves; the length of time they live, their general efficiency and comfort depend very largely on treatment: almost everything, in fact, depends on the physician. Furthermore, in the treatment of chronic disease, a broader view of all the circumstances of the case must be taken than in the treatment of acute disease; facts concerning the nature of the patient's occupation and the state of his family and financial affairs must be taken into consideration. In acute disease these factors enter very little; for the few days during which they are sick, no matter what may be their family or financial responsibilities, all patients with such diseases as pneumonia or typhoid fever usually succeed in having the same excellent treatment carried out.

Great emphasis is laid on the hopefulness gained by this point of view, that in chronic disease, the aim of treatment is improvement in function. Not only students, but also eminent practitioners as well, often show a lamentable tendency to direct all their attention to the anatomical basis of the disturbance to the exclusion of treatment; their whole aim seems to be only to determine as accurately as possible the exact anatomical nature of the lesion present, and, partly because of considering nothing but the anatomical-structural changes, and, realizing

the difficulty, if not impossibility, of influencing these changes, they have shown a tendency to skepticism in their attitude toward the treatment of chronic disease. Another mistake associated with this one is the tendency, not only of the laity but also of many well trained physicians, to consider the so-called "chronic and incurable diseases," as conditions having an inherent downward tendency, and, from the standpoint of therapeutics, hopeless. This point of view is a wrong one: most chronic diseases do not have an inherent downward tendency; they result in a weakness of function and, if the functional activity of the patient is adapted to his functional capacity, the *status quo* may often be maintained. It is a mistake to associate the words "chronic" and "incurable," as they often are, together. The dictionaries (Century, Webster) define "incurable" as "beyond the power or skill of medicine," and give "hopeless" as a synonym. If this definition is correct, we should reserve the term "incurable" for such diseases as the acute infectious diseases, not susceptible of specific treatment, whose course it is "beyond the power or skill of medicine" to directly influence, and not use these expressions with reference to such conditions as heart disease, Bright's disease, diabetes, and many other chronic diseases, the anatomical changes of which we are, indeed, unable to influence, but whose course is most decidedly amenable to treatment, often, indeed, very largely determined by it. The term "incurable" implies that the physician is powerless in the face of the condition. Since the physician is often unable to directly influence their course, we may, therefore, properly use this term with reference to many of the acute infectious diseases, but not with reference to most chronic diseases, for in such conditions he is far from powerless. A wrong point of view regarding the purpose of treatment is responsible for both of these mistakes. To counteract this attitude toward disease, great emphasis is laid on the correct point of view, namely, that in the treatment of chronic disease we try to influence not so much structure as function. A patient whose leg had been amputated would not be sent away with the statement that, since it is impossible for him to grow a new leg, nothing can be done for him; by the use of an artificial leg such a patient can be made nearly as efficient as a normal man. The same attitude should be taken toward patients with incurable lesions of internal organs; these patients, too, can often be made functionally efficient. In examining patients, attention is directed chiefly to the nature and degree of the disturbance of function; in heart disease, for example, it is emphasized that we do not treat murmurs, that in some of the worst cases of cardiac decompensation murmurs are absent, and that, therefore, it is a mistake to pay more attention to murmurs than to the degree of circulatory decompensation as evidenced by the history of the patient. A correct point of view in this respect is of the greatest importance

since it makes for a very great gain in hopefulness.

Since it is only through feeling confident of obtaining good results that the physician,—in the face, often, of great difficulties,—can carry out his treatment with enthusiasm, I believe that it is very important to strongly impress students early in their medical career with an optimistic and hopeful attitude toward the results of treatment. That chronic disease is amenable to treatment and has a hopeful outlook is capable of demonstration, and is one of the things we try to show students. Our optimism regarding the effect of treatment at the hospital where the instruction is given (The Robert Bent Brigham Hospital) is probably much influenced by the fact that we see the results of treatment *with the treatment properly carried out*; the less optimistic point of view of many physicians is often due not to the poor results of treatment but to discouragement at the *difficulties of having treatment intelligently carried out* in private practice; and this distinction we try to bring home to the student. The object of the course is, then, not alone to show how to treat sick patients, but also to demonstrate how much treatment can do, especially for patients with chronic disease.

On account of the fact that it is usually not the anatomical lesion which we treat, but the disturbance of function, and that, in diagnosis, so much attention is devoted to the nature and degree of this disturbance of function, we try, as far as possible, to base our therapeutics on a rational knowledge of the functions of the various organs and methods of influencing these functions, and, therefore, discuss very thoroughly the pathological physiology of the various diseases and our methods of measuring functional activity. Active scientific investigation is going on at the hospital where the instruction is given, and the students are introduced to the problems of scientific investigation so far as these problems relate to treatment. It is pointed out that, whereas the most important practical objects of research in acute medicine are the development of methods of exact diagnosis, the discovery of direct, specific methods of treatment, and the development and establishment of schemes of preventive medicine; in chronic medicine, on the other hand, one of the most important objects of research concerns itself with the development of methods of more exact measurement of functional efficiency, in order that the results of treatment may be more quickly and accurately gauged,—methods that may replace or supplement the less exact guesses of the clinician,—guesses in which the personal equation enters to such a large extent. Notable success in the measurement of functional efficiency has been reached in the case of diabetes; improvement in function,—and, therefore, the effectiveness of treatment in diabetes,—is quickly and accurately determined by measurement of the power of the body to metabolize carbohydrate. A good start

has already been made in kidney disease; the physician is no longer satisfied with the knowledge that the urine contains granular casts, cells, and albumin,—as a matter of fact, in some of the worst cases of chronic nephritis it may be nearly impossible to demonstrate either albumin or casts, and mild cases of nephritis may show much albumin in the urine,—but measured amounts of water, sodium chloride, and dyestuffs are administered, and the amount excreted in a definite time compared with the normal as a measure of the efficiency of the glomeruli and of the tubules in excreting waste products. Possibly the recent studies of the relation of purin metabolism to gout may fulfill a similar function for this disease. At present more attention is being directed to the question of the accurate measurement of functional efficiency, and on account of its bearing on therapeutics this phase of research is emphasized to the students.

The facilities for teaching are excellent. The course is given in a large modern hospital of about 150 beds, well equipped for diagnosis, treatment, pathological studies, and scientific laboratory investigation and with abundant and varied clinical material. While the hospital is one for chronic disease, nevertheless, as a result of intercurrent infection, acute exacerbation, or other reason, many patients with acute conditions come under observation, so that all the common acute diseases such as pneumonia, typhoid fever, the acute stages of rheumatism, appendicitis, gall-stones, gastric ulcer, and tonsillitis are seen during the course of the year. Among chronic diseases, the variety is very great; cases of all the common, and many of the uncommon, diseases of the heart, kidneys, vessels, blood, lungs, joints, bones, nervous system, skin, gastro-intestinal tract and general metabolism are seen at all times. Not only medical methods of treatment, but also, by coöperation of members of the staff, surgical, orthopedic, and other special forms of treatment are demonstrated. Much attention is devoted to the so-called imponderable remedies,—massage, exercise, hydrotherapy, posture, and diet, and the students have an opportunity of observing these methods carried out under the direction of experts.

In the discussion of treatment the plan is to take up first the treatment of diseases of the heart, then, in succession diseases of the kidneys, the vessels, diseases of respiration, the blood, the gastro-intestinal tract, and last, diseases of metabolism. This seems a rational order of discussion: the heart has but one function, that of maintaining the circulation, and, in the treatment of heart disease, there is but one function to be influenced; though the details of treatment may be modified by the nature of the lesion, the general principles of treatment are practically the same, whether the endocardium or the myocardium is the seat of disease, whether the lesion is one of the mitral or of the aortic valve, that is to say, the exact nature of the anatomical

lesion is of far less significance, so far as treatment is concerned, than the question of the severity of the disturbance of function, as evidenced by the amount of venous congestion, edema, dyspnea, or other symptoms of impaired circulation. In the treatment of diseases of the gastro-intestinal tract a new complication is introduced: the gastro-intestinal tract is made up of a number of distinct organs, and each of these organs has several distinct functions; the same general principles,—stimulation of function, and rest of function,—are used, and the degree of disturbance of function is of the utmost importance, but we must first recognize which part of the gastro-intestinal tract is diseased, and which particular function,—motor, digestive or absorptive,—is disturbed before applying treatment. Diseases of the kidney occupy a position intermediate between diseases of the heart and diseases of the intestine. At the present time the treatment can be discussed with the same degree of simplicity as that of heart disease; it depends chiefly on the severity of the disease, on the extent to which waste products are accumulating in the body. There is, however, some difference in function between the glomeruli and the tubules, and a case is occasionally found in which it is chiefly the tubules or chiefly the glomeruli which are imperfectly functioning; in other words, a case in which the exact distribution of the lesion is significant for treatment. In diseases of the general metabolism the disturbance of function often cannot be related to any particular organ, sometimes, perhaps, simply because we do not know which organ is diseased; in other cases, perhaps, because the cells of the body as a whole are involved. In discussing diseases of the different organs, the functions of the organs are very briefly reviewed and then are taken up, in turn, the nature of the disturbances of function which pathological changes in the organ can lead to, methods of influencing these disturbances of function, and, finally, the clinical forms of disease of the organ; the facts are then illustrated by demonstration of patients in the wards.

Instruction is given to small sections of both third and fourth year students. Each exercise lasts one hour; the first half hour is devoted usually to a talk on the general principles of treating diseases of some one organ, the last half hour to an exhibition of patients under treatment. The work would be better carried out, I believe, by having the students first read up methods of treatment on the outside and then having the important features impressed upon them and the methods of treatment illustrated by bedside quizzes; but there is at present neither a text-book nor a syllabus that treats the subject in a suitable manner, and, furthermore, the extensive use of the quiz method of instruction in the subject would mean slower progress in covering the ground than the time at present allotted to the course warrants. New forms of disease are successively taken up and new pa-

tients shown, but the patients already seen are followed from day to day to show the effect of treatment and the necessity for changes in treatment. Emphasis is laid throughout on the *general principles* of treatment; and it is pointed out that whereas the details of treatment,—the particular drug used, the size of the dose, and often even more important features,—may differ with different physicians, yet the general principles of treatment are essentially the same with different physicians, and one physician can, as I do, use the treatment charts of other physicians as good examples of methods of treatment. Many of the patients are seen again by the student under colleagues giving other courses at the school, so that the student is able to complete his picture of the cases by other points of view.

THE WORKMEN'S COMPENSATION ACT AND THE PHYSICIAN.

By HERBERT J. CRONIN, M.D., CAMBRIDGE, MASS.

THAT the medical fees in workmen's compensation cases must be reasonable and should be based on an industrial basis rather than what the traffic can bear; that efficiency of physicians in returning their patients to work at the earliest possible time is now demanded; that adequate treatment be urged for the employees who may be treated in public hospitals; and that the possibilities of state socialism in respect to medicine can be avoided only by the proper co-operation of the physicians with the insurance companies, are some of the points of interest in a consideration of the present problems in relation to the workmen's compensation act in Massachusetts.

"The policy of the Industrial Accident Board is to treat the medical fraternity as a profession," says Dr. Francis D. Donoghue, medical advisor to the Board. "We are straining every effort to make this law what its framers intended it to be. There are constant problems arising which the Board is called upon to interpret; but that is to be expected of all new legislation. So far the law has been an entire success and we hope to see its provisions extended to take in all classes of employees and the benefits larger for all concerned. A clear understanding of the law by physicians will be a great help in avoiding misunderstandings."

The question of fees is still the most important point to the practicing physician. There is no standard schedule of fees. The law in this respect states:—

"During the first two weeks after the injury, and, if the employee is not immediately incapacitated thereby from earning full wages, then from the time of such incapacity, and in unusual cases, in the discretion of the Board, for a longer period, the association shall furnish *reasonable*

medical and hospital services, and medicines when they are needed."

The Board in interpreting the word "reasonable" medical service feel that the charges should be levied on an industrial basis. The charge should be no more than if the injured working-man came to the physician for personal advice and treatment and the bill was not to be paid by the insurance company. In this respect, the insurance companies have complained bitterly that some physicians deliberately pad their bills and make unnecessary visits in compensation cases. They cite instances where a physician makes three calls a day for fourteen days, at \$5.00 a visit, for such trivial injuries as a crushed finger tip!

The Industrial Accident Board have the supervision of the fees under the law:—

"Fees of. . . physicians. . . shall be subject to the approval of the. . . Board. If the association and any physician. . . fail to reach an agreement as to the amount to be paid for such services. . . the board. . . may. . . call for the formation of a committee of arbitration. . . "

Of course in such cases the company must show reason why the bill is contested and evidence given if it is claimed that the bill is padded.

The guide-posts by which the Board determine the amount of fee a doctor is entitled to are:—

- 1. The locality in which he practices; for the man in the mountains of Western Massachusetts does not receive nor expect to receive what the metropolitan doctor does.
- 2. The nature of the injury.
- 3. The standing of the practitioner in his profession.

In common practice, the following fees may be given as an example of what is generally accepted by the insurance companies without protest:—

Office calls	\$1.00
Office calls with an important dressing . . .	\$1.50
House calls of any sort	\$2.00

If there is a large dressing, such as a severe burn, \$2.50 is allowed for a house call.

Numerous questions arise in relation to house calls. For instance, if a man, injured in Cambridge lived in Dorchester, wished the Cambridge doctor who gave him first aid to continue to treat him at his home, can that doctor charge the extra fee ordinarily asked for going that distance? The Board, in such cases, will not allow more than the \$2.00 fee because it feels that there are just as competent men in Dorchester who will treat that man for \$2.00, and if he demands his own physician, he must himself pay the expenses of the visit above \$2.00.

Then there is the question of more than one visit a day. The companies usually refer these cases to the Board for approval unless the case is one of obvious merit.

House calls for an injured upper extremity

are looked upon as worthy of investigation; for it is felt that so long as the man can walk he could go to the office of the doctor and keep down the expense.

Daily dressings of clean sutured wounds are not only disapproved by the best medical practices, but the advisors of insurance companies realize that they are unnecessary and refer them to the Board for approval.

Many other points arise, but the doctor who will live within the spirit of the act, and make his charges fair for the type case he treats, will have no trouble. There are no bad debts in insurance cases. One is always sure of an early payment, and as these cases are constantly occurring he will have other chances of gaining revenue.

The doctor in this state gets a higher return for service than in any other state in the Union where a similar act is in force.

The fees in first aid treatment are about as follows:—

The thorough cleansing of a wound filled with grease and dirt, that takes much time and skill, is allowed from \$3 to \$6, according to the severity of the wound and the after-results with regard to sepsis. The strapping of a fractured rib is granted from \$3 to \$5. Small clean sutures and the incision and drainage of small septic areas are allowed from \$3 to \$5. The fee for an etherizer is from \$3 to \$5 according to the length of the operation. With operations themselves, the fee question is a constant source of controversy. At one time it was recommended to the Board that \$50 should be the maximum for any operation. This is a fair fee for such cases as it is a well known fact among physicians that \$50 is gratefully received for most major operations among the working classes, who choose a private surgeon rather than go to a public hospital. In the smaller operations, such as the amputation of a finger or toe, the fee is from \$5 to \$10, while the reduction and first dressing of a Colles fracture is from \$10 to \$15.

To some it seems that this problem could be best served by a fee table. The insurance companies would welcome a standard set of prices. Yet this would mean that all men, no matter what their qualifications were, would be classed alike under the law. If instituted, it would take away the present elasticity of the act and not allow the fullest possibilities of adequate treatment in cases where the best was needed, regardless of the cost.

When the Workmen's Compensation Act was originally drafted, the Legislature created the Massachusetts Employees Insurance Association, which was to be a mutual company composed entirely of employers with a monopoly of the workmen's compensation business in this state. But amendments were added which allowed all insurance companies to write compensation under the act in competition with the State Association. This competition has produced a healthy

condition in the interpretation of the act, because if the State company were supreme they could not only force a fee table of their own making on the medical profession, but could open their own hospitals and demand that the employees go to them or be refused compensation. Thus the work would be concentrated in a few hands, to the detriment of the profession at large. Most of the companies today are perfectly willing that the employee shall choose his own attendant if that physician is willing to limit his charges to those considered reasonable. In a recent amendment of the law this is considered:—

“Where, in case of emergency, or for other justifiable cause, a physician other than the one provided by the association is called to treat the injured employee, the reasonable cost of his services shall be paid by the association, subject to the approval of the Industrial Accident Board. Such approval shall be granted only if the Board finds that there was such justifiable cause and that the charge for the services is reasonable.”

This clause has justly given the Board the needed power of discretion in cases where the insurance company has attempted to force its physician on an employee who has good reasons why he wants to choose his own.

The contract system, used by some of the companies, is to be deplored. It is natural that the company will try to employ a physician as reasonable as possible and may not always choose the most efficient one. Cases are treated on a wholesale basis, and as the individual fee is so small, the physicians cannot afford to spend but a limited amount of time on a case. This also is not the spirit of the act, which demands the best possible treatment at reasonable prices.

Then again the contract doctor comes immediately into competition with the regular family doctor; for after the injured employee gets acquainted with the contract doctor, he is liable to continue to call on him for other family troubles. Even in ordinary illnesses, the employees themselves are tempted to have the company doctor because they feel that it will probably help them with their employer if there is a question of losing their position.

As it is now, the family physician is being well paid for his services, and the money that was formerly taken out of that family for injuries, now remains and the physician has a better opportunity of being paid if he attends the wife or children.

When the act first went into effect, the insurance companies were distrustful of the doctors. But today this attitude has given way to a more enlightened one. The companies find that the doctors were willing to cooperate and, with the Industrial Accident Board acting as an intermediary of the highest judicial ability, it seems that all future problems can be easily handled with the best interests to all concerned.

Today the companies demand that a man shall

be efficient in his treatment of these cases. A doctor should try to get the patient back to work in the shortest possible time. A man may break his leg and the bone be firmly united in eight weeks, but because of muscle stiffness and atrophy, he will continue to limp around and refuse to go back to work. This man may not be a malingeringer, even in spirit, but he feels that it is necessary for his best recovery to stay away from work until the leg feels as good as before the accident. He is getting his weekly compensation and thinks the company is rich and well able to pay him his dues. If a doctor in such a case will apply the well known methods of active and passive motion with massage and baking, as well as the proper mental encouragement, he can get the man back to his work in a much quicker time. As the law now stands, deliberate attempts at malingering can be partly avoided by this part of the Act:—

“After an employee has received an injury, and from time to time thereafter during the continuance of his disability he shall, if so requested by the association. . . submit himself to an examination by a physician. . . furnished and paid for by the association. If he refuses to submit himself for the examination, or in any other way obstructs the same, his right to compensation shall be suspended and his compensation during the period of suspension may be forfeited.”

The practicing physician is now able to compete with the out-patient departments of the various public hospitals which are charging \$1.00 a visit at wholesale rates. He can give the individual care which is so necessary in these cases if they are to return to work quickly. Visit the out-patient department of the Boston City Hospital any morning and see the treatment given to the industrial cases there! A line of men, daily averaging about 150, are crowded together in a small room, examined hastily by an externe, and passed on to the dressing room, where the treatment is applied by a student or attendant, whose main idea is to slap on bandages, get the patients out and have them return as few times as possible. Septic cases are herded together with clean wounds, and the student dresser goes from one to another. Is it any wonder that the clean cases go septic and then twice the time is necessary for their recovery? The same conditions prevail at the Haymarket Square Relief Hospital. Ninety per cent. of the traumatic surgery that comes into this hospital is treated by students who have no interest in the case and will never see it again. Their aim is to get the cases fixed up as quickly as possible and then refer them to the Main Hospital (City Hospital) for their after-treatment. Every case is first seen by a house officer, and if he considers it serious, or it happens to be a railroad accident case, which means a court fee to the resident surgeon, then the house officer will show the case to the resident surgeon, who will give him advice as to the treatment. I have

seen an injury as serious as a punctured wound of the knee joint in a child treated, with the knowledge of the resident surgeon, by a third-year medical student!

There is springing up at present a type of so-called emergency hospitals, which are masquerading under the guise of charitable institutions, but really are preying on industrial cases. Here again it is wholesale treatment with not the best interests of the patient at heart. Such hospitals should not get the same compensation as the family doctor and efforts should be made to discourage their growth.

The records of physicians and hospitals are notoriously poor in the industrial cases. There should be a complete record kept and especial note made on the the end-result of the injury for reference to the Board and especially in court proceedings.

The question of charges for board and room in hospitals along with special treatments of various sorts, such as x-rays, etc., has been solved for the present as follows, according to the Board's Annual Report:—

"The Industrial Accident Board approves the following fees by hospitals:—

1. The fee for hospital care in all cases shall not be more than \$15 a week, in addition to the following extras:—
2. Operating room fee, \$5.
3. X-ray, \$5 for each examination, without regard to the number of plates made, except for examinations of the head, trunk or hips, when a charge not to exceed \$10 may be made.
4. Serums, special drugs and special appliances may be charged for at cost.
5. When it becomes necessary to engage a special nurse for more than three days, the insurer should be notified, and have the right to bring the matter to the attention of the Industrial Accident Board for investigation as to the necessity for the engagement of the nurse and the extent of nursing required. The maximum charge per day for such special nursing shall not exceed \$4.
6. The board will approve a charge, not to exceed \$3, for ambulance calls within a radius of three miles, and \$1 for each additional mile, the charge to be made only in one direction.
7. The fee for out-patients shall not exceed \$1 for each visit.
8. When a surgeon is employed to care for an injured person and such person is admitted to the hospital, or when the custom or rule of the hospital provides that a patient shall pay the surgeon's fee, the Board will approve of the payment of a reasonable fee to the surgeon, in addition to hospital charges."

The question of x-rays has been much abused. It is felt that the x-ray should be taken only in case of doubt and then that the fee be allowed only to an expert. The promiscuous taking of pictures by general practitioners with a poor machine, which results in a plate of little or no

use, does not come within the meaning of this ruling.

There is now a feeling that the staff of no hospital should be allowed to charge a fee for the care of industrial cases. Such doctors would then probably make a more concerted effort to get these cases out of the wards if there were no daily income for them while they remained there. The corralling of cases by the staffs of some of the public hospitals and making private patients out of them, is much to be deplored and should not be countenanced.

There is no question that the proper application of the Workmen's Compensation Act will prevent any relapse into state socialism for the medical profession, such as is now in force in England and Germany.

A METHOD OF TESTING GASTRIC SECRETION BY THE USE OF A SELF-CLOSING DREDGE.

BY ALEX. M. BURGESS, M.D., PROVIDENCE, R. I.

Of the many attempts which have heretofore been made to find a method of obtaining a sample of gastric contents without the use of a stomach tube, none has been absolutely successful. The failures are due chiefly to the fact that contamination with esophageal and pharyngeal mucus has been found unavoidable. Among such attempts may be mentioned the use of a small sponge on a thread, the Einhorn bucket, and the thread test. A method recently suggested by Rehfuß of Philadelphia, which involves the use of a steel capsule containing capillary tubes filled with agar is, however, not open to this above-mentioned objection. In this instance the gastric juice enters the capsule by several small perforations, and alters the color of the indicator which is contained in the tubes of agar. On removal, the action of esophageal and pharyngeal mucus is practically negligible and can affect only the extreme ends of the agar tubes. Thus the question of the presence of acid in the gastric secretion is answered, although no actual sample of the secretion is obtained.

During the summer of 1915, while working in the Ewald Clinic at the Augusta Hospital in Berlin, there occurred to the writer the fundamental ideas on which the following method is based.

This method consists of the use of a capsule, which is so constructed that it automatically closes as it leaves the stomach, and thus protects its contents from contamination. This automatic closure, the essential feature of the capsule, is made possible by the fact that the

FIG. 1.

Diagram of Dredge Threaded with Silk, and with Parts Separated.
 A—Silk thread.
 B—Glass cover of dredge.
 C—Crossed platinum wires, with thread passing beneath them.
 D—Hollow part of lower portion of dredge.
 E—Solid glass.

cover (see diagram, Fig. 1) is perforated by a small hole, through which passes the silk thread to which is attached the lower part of the capsule. Thus the cover is free to move upon the thread. When the dredge, as the capsule may appropriately be called, in being removed from the stomach, reaches the cardia, the cover is forced down upon the lower portion, and it is thus effectively closed and may be drawn up through the esophagus without any chance of contamination of its contents. The cover should not fit the lower portion tightly, but should be about 1 to 0.5 mm. greater in diameter than the outside diameter of the latter. This allows the cover to slip down easily over the lower portion when it meets resistance from above.

As important as the effective closure of the dredge on leaving the stomach, is the effective opening and filling after it is introduced. This is accomplished by placing it in an ordinary gelatin capsule which fits closely around it, and allows it to be swallowed while open, the parts being held separate within the inclosing capsule, and as soon as the gelatin is dissolved in the stomach, the dredge readily fills with fluid. At body temperature the gelatin dissolves sufficiently to allow the dredge to fill in from one to five minutes, but fifteen or twenty minutes should be added to allow for further solution of the gelatin so that there may be no interference with the closure of the dredge in its removal.

The problem of weighting the dredge so that it may be readily swallowed, and so that it will sink in water, is solved by having half of the

lower portion made of solid glass. Mr. A. W. Clafin, of George L. Clafin and Company, Providence, has been successful in devising and producing this dredge for me. A detailed description of it follows:—

FIG. 2.

Dredge closed.

The dredge consists of two parts, a lower portion and a cover. The lower portion is cylindrical (see Fig. 1) with rounding base, and one-half of it is solid glass. The walls of the upper cup-shaped half of the lower portion are 0.5 to 0.75 mm. in thickness. The opening at the top is spanned by two pieces of No. 26 platinum wire, crossed at right angles, and with their ends securely embedded in the glass. These wires are slightly curved and are set with the convexity of their curves upward. The upper portion, or cover of the dredge is dome-shaped, and half as long as the lower portion. It is perforated at the top centre by a minute hole, sufficiently large to allow it to slide back and forth on two strands of No. 9 surgical silk, which pass through it. This hole is carefully fire-polished so as to leave no cutting edge. The inside diameter of the cover is 0.5 to 1 mm. greater than the outside diameter of the lower portion, so that it may fit down easily over the latter. All edges are carefully fire-polished.

Four sizes have been used; their measurements as follows:—

	No. 1.	No. 2.	No. 3.	No. 4.
Length of lower portion in mm.....	10	13	17	20
Length of cover in mm.....	5	6	8	10
Outside diameter of lower portion....	4	5	7	8

NOTE.—Gelatin capsules which have been used with these dredges are No. 2, No. 1, No. 00, No. 000.—Eli Lilly and Company.

Method of using the dredge:—

The dredge should first be threaded with No. 9 surgical silk, by passing the silk first through the perforation in the cover from above, then beneath

the crossed platinum wires of the lower portion, and back through the hole in the cover from beneath. The silk should be drawn through and cut so that the dredge is strung upon a double thread of about 70 centimeters in length. The cut ends are tied together. The dredge is then fitted into the proper sized gelatin capsule in such a way that the two parts are held separate within the closed gelatin covering. They may be made to adhere to their respective gelatin coverings by the use of 50% alcohol, although in actual use this procedure has appeared to be superfluous.

FIG. 3.

Dredge within gelatin capsule ready to be swallowed.

Immediately before being swallowed, first the thread and then the gelatin covering of the dredge should be moistened with cold water. A little water may be taken to aid in swallowing the dredge. When it has been swallowed and has drawn down almost all of the silk thread, the remaining loop with the knot may conveniently be held beneath the upper lip, or the knot may be slipped between two teeth. There is no discomfort from the presence of the thread while the dredge is in the stomach.

In removing the dredge, gentle and steady traction is made on the thread until the dredge sticks at the level of the cricoid cartilage. A little water may then be taken in the mouth and the dredge removed without difficulty at the moment the water is being swallowed. If several repeated tests are to be made following a single test meal, it is, of course, necessary to swallow and remove the dredge without the taking of water, and this can ordinarily be done without difficulty.

By the use of the dredge an adequate qualitative examination of the gastric contents is possible without the discomfort to the patient which attends the passage of the stomach tube. With the two smaller sizes it is convenient to use a bit of congo red paper in the dredge to indicate the presence of hydrochloric acid, and to transfer a little of the fluid to a slide with a capillary pipette for microscopical examination. The

capacity of the two larger sizes is such that 0.1 c.c. or more of gastric contents is obtained, and with care an accurate titration of the acidity can be made. For this purpose it is convenient to use N/200 NaOH solution in an ordinary burette. By the use of the larger dredges it is possible to carry out, if desired, a study of the variations of acidity in the course of gastric digestion, as is done by Rehfuess and his associates, using his modification of the Einhorn duodenal tube. To the practising physician, however, the dredge will prove most useful in those cases in which he feels the need of a simple examination of gastric contents, but does not feel justified in putting his patient through the ordeal which is often involved in even the most skilfully performed passage of a stomach tube.

Clinical Department.

SUNSHINE: ITS NEGLECTED ANALGESIC-SEDATIVE ACTION.

BY JOHN BRYANT, M.D., BOSTON.

THE healing power of the sun has been known, one might almost say, for countless ages, and it is common knowledge that it makes one "feel good" to go off on a vacation and get one's skin tanned a mahogany color by the sun, even at the expense of a few blisters. Modern scientific application of this knowledge is, however, curiously limited. Solaria are numerous enough, but there is little attempt to get direct application of the sun to the skin, except in the case of the artificial Finsen light for lupus, or more recently in the case of bone and joint tuberculosis, as at Leysin by Rollier.

Since Rollier is one of the foremost, as also one of the most successful, exponents of the virtues of heliotherapy, it may be worth while to inquire what of his methods are available elsewhere. It was the author's privilege to leave Lausanne early one perfect May morning, and after following the border of the Lake of Geneva, to mount rapidly to the three to four thousand foot elevation of Leysin. The first impression is of the extreme beauty of the location, having as it does the snow-capped Alps and Mont Blanc, for its keynote. The second impression one receives, on walking through the village, is of the superlative health and positive optimism of the sick people to be seen on every house balcony.*

Next, one notices the architectural arrangements of the buildings of Rollier's clinic, imposed by the necessity of securing privacy for individual patients during insolation. Arrived

* At this time there were 1200 tubercular patients in the town, and for want of more beds there was a waiting list covering all Europe. Austrians were in greatest number, and the list was long enough so that an applicant was fortunate if he arrived after six months' endeavor.

FIG. 1.—Rollier's Sanatorium, Les Frênes, Leysin.

at the clinic; it was impossible to avoid asking the exceedingly capable head nurse what food it was that made possible the universal ruddy cheeks and smiles and cheerfulness of the patients. She replied that neither children nor adults were stuffed. Her recipe seemed to be plenty of sunshine inside and out, and plain wholesome food and not too much of it. Faith

FIG. 2.—Children's Ward, Leysin.
Showing open-air treatment in summer.

FIG. 3.—Leysin.
Sun cure in winter by Dr. Rollier's method. Clothing consists of hat, short tights, and shoes. This costume is possible owing to the extreme dryness of the snow and air at the considerable elevation of the clinic.

in the future must be an important element in the condition of universal mental bliss to be found here, for it seems practically certain that, even though the time may be two or three years, the invalid may look forward to discarding props and crutches, and to returning home cured.

The technic of insolation has been fully described by Rollier and others, and it is only necessary to say that the sun is very powerful, and that it is capable of producing harm as well as benefit when not properly controlled. Of chief importance for immediate consideration is the fact that during the process of insolation, pain ceases, and nervous irritability decreases or disappears.

It is obvious that tuberculosis is not the only disease marked by pain and hyper-irritability of the nervous system, and it seemed reasonable that some of Rollier's principles could well be applied to other problems in medicine. True, his stage-setting cannot be moved, and the elevation and air may not be the same in other places, but the sun is not always behind the clouds or hidden in smoke or fog, even in New England. Therefore, when occasion arose, it seemed highly desirable to try an experiment in home insolation,—for want of the hospital facilities at Leysin. The experiment has been justified by its results, as suggested by the two following case histories:—

CASE 1. Mr. G., age 45, was first seen when in a practically hopeless condition, suffering from atrophic arthritis. Pain was incessant, and it was impossible for him to remain more than fifteen minutes in any position, day or night. Pain and restlessness were only partly relieved by a change in diet and other medication. As his bedroom window faced south and the sun was imitating that of Egypt, his bed was placed by the window with due precaution against draughts, and his body was increasingly exposed to the sun, devoid of all clothing. By the time he could remain for an hour or two in the sun, the change was astonishing. He remained quiet, dozing, contented, apparently free from pain and no longer begging to be turned, during the whole of his sun baths. A decided improvement was shown during the remainder of the day and night interval, but during the exposures complete comfort seemed to be attained. Though insolation did not alter the final result, the increased comfort attained was apparently appreciated, not only by the sufferer, but by the others most nearly concerned.

CASE 2. Mrs. F., aged 38, was referred for treatment of extreme emaciation and visceroptosis. When first seen, although the height was 5 feet 7 inches, the weight was 87 pounds, the upper arm apparently being only slightly larger than the wrist. Nervous irritability was extreme, the patient stating that every nerve in her body was jumping all the time. She was, in short, an example of the state to which injudicious treatment can bring the feminine carnivore of extreme type. Diet and other measures rapidly added fifteen pounds to her weight, with corresponding improvement in general condition and in "the nerves." But as in the first case, the measure from which the greatest relief was obtained, was the sun bath. When the exposure had reached an hour a day for the whole body, the "nerves" practically disappeared, to return at once as soon as for sufficient reasons it was impossible to give the time to continuing the sun baths. At present the patient remains in a satisfactory condition, despite severe drains upon her strength and

powers of resistance, and she is confident that further progress will be uninterrupted as soon as arrangements can be made for continuing the insolation.

These two cases prove sufficiently the possibility of bringing the beneficent action of sunshine to the individual, where it is not possible to provide efficient hospital facilities for insolation. Such hospital facilities do not, so far as the author knows, exist in this vicinity. This applies not only to the tubercular, but to the many other cases suffering from chronic pain, especially in the bones or joints, or from nervous hyper-irritability, or both.

Sunshine, when properly used, has both a powerful analgesic and a sedative action. It is to be hoped that if hospitals or sanatoria cannot be equipped for giving patients adequate insolation, advantage may at least be taken of the value of carrying out this efficacious form of treatment at the home of the individual sufferer. In a word, sunshine is a simple, cheap, and efficient analgesic-sedative, of which more extensive use can be made with correspondingly gratifying results.

NEUROMA OF ULNAR NERVE: ANALYSIS OF A CASE.

BY JAMES B. AYER, M.D., BOSTON,

Assistant in Neurology and Neuropathology, Harvard Medical School; Assistant Neurologist, Massachusetts General Hospital.

THE following case is worthy of publication, on account of its manifold teachings and interest to neurologist, surgeon, pathologist, and physiologist. A cut across the elbow, insignificant at the time even to the eye of an expert, leads later to complete ulnar paralysis, the formation of a painful tumor, and three operations, with serious residual palsy after six years.

Without further introduction, let us read the case in summary (italics being used to accentuate matters considered of importance in the general understanding of the case).

R. W., in May, 1909, when thirty-four years of age, accidentally cut her left arm just above the elbow with a knife; the wound was sutured and *healed in two weeks*. A few weeks later, July 27, 1909, on account of a feeling of numbness in her little finger she was seen by the visiting neurologist at the Massachusetts General Hospital, who found motion and sensation present in the ulnar nerve distribution and makes note "*apparently no nerve involvement*." When the patient returned next on Oct. 21, 1909, anesthesia, pain, weakness, R.D., all referable to the ulnar nerve, were unmistakable, and operation was advised.

On Jan. 8, 1910 (eight months after the injury) operation was performed: "Old scar at elbow excised—ulnar nerve located and found largely cut across, cut ends freshened and approximated with int. silk. *Nerve apparently imbedded in scar tissue which was not disturbed.*"

The patient after leaving the hospital did not return for four years. On Feb. 17, 1914, she was seen by the writer and gave the following story: *No improvement had followed the operation; she still has pain and tingling over ulnar distribution, and has also had for two years a small painful mass in the scar of the old operation, and thinks it is growing larger.* Neurological findings: "Anesthesia in ulnar distribution, left hand. Pain in same region. Loss of ulnar power in hand, wasting of interossei. R.D. of ulnar muscles. Mass in scar." (W. E. Paul.) Surgical interference was advised, and on Feb. 19, 1914, Dr. C. A. Porter performed the following operation:—

"Five-inch incision, *excising old scar. Ulnar freed.* A nerve bulb, size of end of finger, found on proximal end of nerve. This was connected by a few shreds of tissue—two to three mm. in diameter with the distal ulnar. This thinned portion of the nerve was about one inch in extent. Bulb and thread-like portion excised and slight tension was made upon proximal end. Nerve united by two chromic No. 00 catgut sutures, put up with arm extended. Cargyle membrane about suture. Fat over

PLATE I.—Ulnar nerve and neuroma freed from bed of scar tissue, as they appeared at operation, 1914. Approximately two-thirds actual size.

PLATE II.—Neurofibroma. $\times 60$. Shows whorls of myelin. This is characteristic of the whole tumor.

PLATE III.—Neurofibroma. $\times 1000$. Shows individual myelin sheaths which compose the whorls seen in Plate II.

PLATE IV.—Cross section of nerve distal to tumor, the portion freed from scar tissue at operation. At least two-thirds of the "nerve" is connective tissue. $\times 13$.

PLATE V.—Detail of small bundle appearing in Plate IV, showing individual nerve fibres interspersed with masses of fibrous tissue. $\times 70$.

PLATE VI.—Detail of Plate V. Shows normal nerve fibres surrounded by and intermixed with islands of connective tissue. $\times 1000$.

PLATE VII.—Shows marked atrophy of thenar and hypothenar eminences of left hand with tendency to "claw" appearance.

nerve and skin closed with S.W., interrupted. Arm extended in splint."

Feb. 28. Wound healed by first intention.

March 2. Arm flexed at right angle. Internal angular splint. Discharged.

On May 23, 1914, she returned and was seen by the writer because *another tumor* had formed above the scar; it was very tender and pressure caused pain in little finger. There were the same evidences of ulnar paralysis as before. This tumor was not interfered with and, as she stated subsequently, *it soon went away*.

On sending for her, the patient again returned one year later, on Feb. 6, 1915, saying that strength and feeling were the same as before the last operation, but that she was now *free from the pins and needles sensation*, and there was no pain or tenderness. On examination most of ulnar muscles showed sluggish activity and reacted to faradism. There was still considerable atrophy of the hypothenar muscles, and the characteristic ulnar deformity of the hand. Epieritic sensation absent.

Pathological examination of the tumor and attached nerve follows:—

The material consists of a firm bulbous mass, 1.5 by 1.5 by 0.8 cm. in size, from one end of which protrudes a tissue of similar consistency, oval in cross section, measuring 8 by 5 mm., simulating in size and consistency a normal ulnar nerve the whole forming a discrete bit of tissue, encapsulated, except at the cut ends.

On sectioning, the *bulbous mass* is found uniformly dense, and on staining this tissue is found to be almost entirely composed of myelin sheaths arranged in whorls—for the most part the myelin is continuous about a central unstained axis, similar to its appearance in normal nerve tissue.

The appended portion, the *ulnar nerve* distal to this tumor, is most interesting, and requires detailed study.

The cross section 2 cm. below the tumor shows the tissue arranged in bundles, and on staining, these bundles are found to be of different nature; approximately two-thirds of the cross section is occupied entirely by connective tissue, for the most part of recent formation, though some is of long standing. The remaining one-third consists of several bundles of loose connective tissue, with numerous isolated nerve fibers in its meshes; in places, nerve fibres are in bundles, but in such case the bundle is surrounded and interspersed with dense and young connective tissue, and the myelin in such cases is seen to be greatly disintegrated, assuming the appearance of periaxial degeneration.

In a single cross section of the "nerve" at this point one may see a normal nerve fiber with myelin sheath intact, a group of two or three nerve fibers with connective tissue between, larger groups of degenerated nerve fibers surrounded by and interspersed with connective tissue, and areas of dense connective tissue still in the shape of the above-described islets, but with no vestige of nerve tissue remaining.

One more microscopic finding. In the meshes of the "nerve," most prominent both as to size and number in the neighborhood of the tumor, are seen long uniformly staining fibers and fibrils, not seen to branch, but to change their course frequently or run straight for seemingly indefinite distances. These fibrils are stained only by the Weigert method.

We are undoubtedly here dealing with a neuroma of the ulnar nerve,—a true increase in the nerve elements. Interest, however, centers chiefly about the portion of the nerve distal to the tumor. Two-thirds of this "nerve" by bulk is made up of connective tissue, and in the remaining third there are few nerve fibres, and most of these are not normal. What is the state of the nerve elements at this point? There is every reason to believe that there is a progressive degeneration of the nervous tissue and substitution by connective tissue, and that this process has been going on for months. It is impossible to state the underlying cause, or whether destruction of nerve fibres by connective tissue is the primary process. The appearance of the tissue at operation, however, an excessively dense scar tissue (from the accident four years previous) surrounding the nerve in question, places the suspicion on the connective tissue as a cause of pressure, and ischemia, with consequent nerve destruction.

SUMMARY AND DISCUSSION.

Let us review this case with the facts in mind, in order to interpret the findings and their significance.

When first seen the patient had no ulnar paralysis, evidently then the nerve had not been greatly affected by the original knife-cut, and we are forced to believe that the disability was largely due to the formation of scar tissue during the healing process, and found at the second operation.

Recently, in this connection, F. C. Cotton¹ has shown the frequency and mechanism of similar ulnar palsies from fractures of the elbow, due to scar tissue formation.

As the nerve was not removed from its bed of fibrous tissue in 1910, rejuvenation of the nerve was evidently impossible, and we find a painful and tender tumor, which is shown to be a true neuroma, *i.e.* whorls of myelinated fibers, gradually developing immediately above this obstruction. There is also found an atrophic condition of the nerve distal to the tumor in the area of the scar tissue, showing about two-thirds connective tissue and one-third nerve tissue, the two arranged in such manner that one is forced to believe there had been a slow attrition of the nervous elements, and replacement by the lower type of tissue: the mechanism of this process is best considered as one of compression and ischemia.

After excision of the tumor and of the scar tissue surrounding the nerve, we find a relief from the local pain and the tenderness, and also of the paresthesiae of the fingers, but a return of function only equivalent to that previous to operation. From this it would seem that the paresthesiae were symptoms of irritation of the nerve fibers, and that with removal of the source of irritation these symptoms disappeared, together with local pain and tenderness in the region of the tumor. That more function is not regained may be explained by a loss of vitality of fibers so long out of use, very likely leading to an atrophy of their cells of origin in cord and ganglia.

The second tumor, appearing soon after the operation in 1914, caused anxiety at the time, but its rapid and complete disappearance suggests that it was an exaggeration of the physiological "primary end bulb" of Ballance and Stewart,² and not a true neuroma.

What, then, may we learn from this case? Of interest to the pathologist and physiologist is the progressive formation of scar tissue with consequent progressive degeneration of nerve fibers, resulting in corresponding motor and sensory loss.

The formation of a true neuroma above the area affected suggests the cause of its growth as an attempt of nerve fibers to regenerate, aborted by obstruction distal to it.

From observation of the return of function one year after supposed freeing of the nerve it would appear that regeneration of fibers, shorn of their function for a period of four years, was impossible in this case.

The formation of a second small tumor at the end of the cut nerve of temporary existence, supports the contention of the importance of the "primary end bulb" in regeneration of a peripheral nerve.

To the clinician, neurologist and surgeon, the case teaches the importance of never allowing ourselves to be deceived by an apparently slight accident when in the region of a nerve (perhaps especially in the region of the elbow); if progressive disability occurs, due to nerve involvement, thorough surgical investigation is indicated, with complete freeing of the nerve from scar tissue as early as possible, and precautions taken to prevent the formation of a similar situation. If delayed several years, regeneration may not take place—even though the path for such be carefully prepared.

In the above criticism no excuse is necessary for the physicians and surgeons who dealt with the patient; an absence of the patient for four years at the most critical period is the chief cause of the above train of pathological events.

Book Reviews.

The Fundamental Basis of Nutrition. By GRAHAM LUSK, Professor of Physiology, Cornell University Medical College and Scientific Director of the Russell Sage Institute of Pathology. New Haven: Yale University Press. 1914.

This monograph is the reprint of a lecture delivered by the author in November, 1913, as the anniversary address of the New York Academy

of Medicine. It may be regarded as the nucleus of Dr. Lusk's larger work, "The Elements of the Science of Nutrition," reviewed in the issue of the *JOURNAL* for July 21, 1910 (Vol. clxiii, No. 3). It is intended ultimately for the educated laity, to afford them a better understanding of the principles of nutrition than can be derived from current popular writing. After a brief historical survey of the subject, the elements of nutrition are considered under the aspects of constant need of fuel and protein. Habits of diet are discussed and beriberi is described as a typical disease due to diet deficiency. The criteria of the monetary value of foods are analyzed and there is a useful index of dietetic terms. The book should be of value as a compendious manual in conjunction with the author's larger work.

The Difficulties and Emergencies of Obstetric Practice. By COMYNS BERKELEY, M.A., M.D., and VICTOR BONNEY, M.S., M.D. Second edition, with 302 illustrations. Philadelphia: P. Blakiston's Son and Company. 1915.

This book is an excellent reference book on obstetric complications. There is no book, so far as the reviewer is aware, that brings such a vast amount of material together in such a readable form.

In spite of its many excellent points, there is much that the reviewer cannot agree with; as, for example, the authors advise irrigation of a breast abscess several times a day with hydrogen peroxide; and again, in a forceps delivery they state that when the head has been brought down on the perineum the forceps may be removed and the uterus allowed to expel the child. The authors naturally advise the left lateral position for doing forceps operation, and there can be no criticism of that position, but when the illustrations show the operator's left hand over and about the anus, the reviewer cannot but feel their "aseptic conscience" is not what it should be. The chapter on artificial feeding of infants is totally inadequate and has absolutely no place in such a work. Notwithstanding these criticisms, the volume is a real addition to one's obstetric library.

A Practical Treatise on Diseases of the Skin. By OLIVER S. ORMSBY, M.D., Professor of Skin and Venereal Diseases in the Rush Medical College, Chicago. Octavo, 1168 pages, with 303 engravings and 39 plates in colors and monochrome. Philadelphia and New York: Lea and Febiger. 1915.

Of late years text-book has succeeded text-book on the subject of dermatology, with astonishing rapidity. A large number of these are by American writers. Many of these have attained considerable excellence. Ormsby of Chi-

cago is the last one to take up his pen, and he has produced a very good book of its kind. In one respect the book merits great praise and shows great improvement over most of the recent publications, and that is in the clearness and decisiveness of its literary style. Too many that we have lately been introduced to seem to disregard totally a clear mode of expression. Ormsby's book does not go into details so much as many of its immediate predecessors, and there are fewer references to the literature.

The illustrations are excellent and the type good. It is a conservative book in its attitude to etiology and diagnosis, as well as in its paragraphs on treatment. It will be a safe and valuable book in the hands of the general practitioner.

Collected Papers of the Mayo Clinic, Rochester, Minnesota. Edited by MRS. M. H. MELLISH. Vol. VI, 1914. Philadelphia and London: W. B. Saunders Company. 1915.

The sixth volume from the Mayo Clinic for the year 1914 consists of eight hundred pages; its general appearance and red binding are now familiar to all surgeons; it has the same beauty and prodigality of illustrations and the same accuracy of imprint. Thirty-one contributors have written eighty monographs, which are classified, as usual, under the general heads of Alimentary Canal, Urogenital Organs, Ductless Glands, Head, Trunk and Extremities, Technic and General Papers. We are impressed by the appearance of such papers as "Choice of Method in the Removal of the Eyeball" and "Tonsillectomy in Children from the Standpoint of the General Surgeon," also "Intestinal Parasites of Minnesota," since one would not expect to find them in reports of clinics which are essentially devoted to general surgery.

It is this year, as usual, impossible to criticize adequately and briefly the collective papers of the Mayo Clinic. A large number of them are valuable monographs based on an enormous number of cases, and almost all of the others are the results of hard work or long experience of highly trained specialists.

The book has become an essential element in the library of every progressive surgeon. It makes available to the reader in a very practical form the practice and results which characterize this extraordinary and essentially American surgical clinic.

The Psychology of the Kaiser. A Study of his Sentiments and his Obsession. By MORTON PRINCE. pp. 112. Boston: Richard C. Badger. 1915.

As an analyst of human character Dr. Prince is always interesting and suggestive. In this small brochure the attempt is made, with what measure of success the future alone can show, to

explain the present world happenings in relation to certain obsessions of the German Kaiser. It is Prince's belief that the Kaiser sees in the Social Democratic party a menace to his deeply rooted wish to be the autocratic ruler of Prussia and the German Empire. By the acceptance of the theory of the divine right, he finds a means for the fulfillment of his wishes which the rising tide of democracy throughout the empire is menacing. Under these conditions, from a psychological standpoint, the defensive instinct of fear has been very vigorously aroused, and this fear is not far removed from the emotion of hate which, in the minds of many writers, has been the predominant attitude of Germany as represented in the Kaiser, especially toward England. Or, as Prince more definitely puts it, the egocentric sentiment of the Kaiser and his fear for himself and his empire, although possibly subconscious, induces an emotional defense reaction. "This defense reaction is anger and the sentiment of hatred." The chapter headings of the book are as follows: The Kaiser's Antipathy, The Kaiser's Prerogatives, The Kaiser's Divine Right Delusion, The German Autocracy and the Army, The Kaiser's Sentiments, The Kaiser's Self-Regarding Sentiment, Aims of the German Democracy, The Real Cause of the Kaiser's Antipathy, The Kaiser's Antipathy an Obsession and a Defense Reaction. It is inevitable that this well written discussion of the Kaiser's personality will be read with varying feelings. It will doubtless appeal rather to the psychologist and to those familiar with modern psychological methods than to the man in the street. The validity of its conclusions is dependent largely upon the acceptance of the premises, and these may well be open to question. It is, however, from the psychological standpoint a fair, if not generous, analysis of perhaps the strongest personality of our time. It will not, we venture to suggest, prove universally convincing.

Diseases of the Skin. By JAMES H. SEQUEIRA, M.D., Lond.; F.R.C.P., Lond.; F.R.C.S., Eng. Second edition. With 48 plates in color and 238 text figures. Philadelphia: P. Blakiston's Son and Company. 1915.

In the preface to this, the second edition of his book on skin diseases, Sequeira announces that many articles have been rewritten and that there are numerous additions. A series of microphotographs, illustrating the histology of many common affections, is a new feature. There are four new colored plates and 60 new figures in the text. The microphotographs are good, but the colored plates impress us as only fair. Most of the figures in the text are well up to modern standards. The book is thoroughly English in tone and spirit, and is not overburdened with a recital of conflicting views. The paragraphs devoted to treatment show conservatism and freedom from discursiveness.

NEWSPAPERS AND PATENT MEDICINES.

THE JOURNAL has received communications severely criticizing the Boston dailies for their advertisements of patent medicines and medical frauds, and urging it to call the attention of its readers to the matter. An examination of these papers certainly shows that some of them at least are not taking an advanced stand on this subject. In fact, most of them are behind the stand taken by some of the dailies of a section of the country which has recently come in for severe criticism on the part of Boston editors. Thus two years ago the *New Orleans Item* announced that it would not print any medical advertising that the most searching examination would be "violative of truth" or "void of probability." Nor have Boston and Massachusetts, leaders in so many movements for the public good, been conspicuous, at least in recent years, for an advanced stand in regard to patent medicines. Thus Boston is far beyond New York City, the Board of Health of which last

year adopted an ordinance requiring either the registration of the name of ingredients of all proprietary or patent medicines with the board of health, or, in lieu thereof, the printing of the name of each ingredient "conspicuously, clearly and legibly in English, on the outside of each bottle, box or package in which the medicine or medicinal compound is held, offered for sale, sold or given away." The Louisiana State Board of Health adopted the ordinance *verbatim*, and several Western cities and states have under consideration the enactment of similar legislation. The General Assembly of Louisiana last summer adopted a concurrent resolution approving the campaign of the State Board of Health "to rid the State of Louisiana of the pernicious patent nostrums so widely advertised and sold under misleading and fraudulent pretences as to curative properties"; the General Assembly further commended the action of the Louisiana Press Association for its unanimous endorsement of the State Board of Health in its effort to control the patent medicine evil.

Returning to the newspapers: it is interesting to note that the Louisiana Press Association, in addition to endorsing the fight of the State Board of Health on patent medicine frauds, requested the president of the board to furnish the press of the state a list of these nostrums so that they might be banished from the advertising columns. This action is significant in that it shows that newspaper editors who really desire to exclude fraudulent advertisements from their columns find no difficulty in securing expert advice on the subject. Some American newspapers submit their medical advertisements to the American Medical Association for its opinion before publishing them, just as many newspapers consult authorities on stocks, bonds, mines, etc., before accepting advertisements of questionable concerns.

That most of the Boston dailies do not make any serious effort to exclude fraudulent patent medicine advertisements from their columns will be evident to our readers if they will glance over almost any issue of almost any of them. They will find there numerous cases of advertising "violative of truth" and "void of probability," as well as of numerous nostrums the true character of which has often been exposed, such as Eckman's Alterative, "a mixture of alcohol, calcium chloride and cloves, which every intelligent physician knows is perfectly worthless for the cure of consumption, sold at

an exorbitant price—\$2 for eight ounces—under the cruelly false claim that it will save the tuberculous"; Lydia E. Pinkham's Compound; "Plant Juice"; cures for diabetes, kidney and bladder diseases, foot drafts for rheumatism, asthma cures, hair growers, fat reducers, "flesh builders," etc., etc. Especially numerous seem to be those patent medicines which are ashamed to sail under their true colors and are recommended in the columns entitled "Today's Beauty Suggestions," "The Doctor's Advice," etc.; here we find such "simple" things as "spurmax," "canthox," "eadomene," "hypo-no-nuclane," "balmwort," "sulpherb tablets (not sulphur)," "arbolene," etc.

One of the most interesting examples of the strange bed-fellows which the proprietary medicine and food business makes is frequently to be seen in the advertisements of Sanatogen in the newspapers. Sanatogen, a mixture of 95% casein (better known to the public as cottage cheese) and 5% sodium glycerophosphate (a substance of no therapeutic importance) has been carefully examined by the American Medical Association and the falsity of the claims made for it pointed out. It is a product of German origin, and it is rather amusing to see the large advertisements of Sanatogen, including the enthusiastic endorsement of Sir Gilbert Parker, who has recently been flooding medical men of the United States with anti-German literature.

The history of Sanatogen contains a lesson for physicians, for the latter have contributed not a little to the success of this proprietary food-nostrum; without informing themselves as to its true composition or value, but accepting the statements of the manufacturers, not a few have recommended it to their patients, without any suggestions as to its limitations as a food or its exorbitant price. Unfortunately, other instances of the manner in which physicians have unwittingly aided the exploitation of drugs as patent medicines are to be found. Last spring we noticed in an advertisement of patent medicines at cut rate prices, the name urotropin immediately preceding, we believe, "Var-ne-sis," a typical nostrum of the rheumatism-cure type. Urotropin, of course, is merely a copyrighted name for the U. S. pharmacopoeial hexamethylenamine; as "urotropin" it has been advertised by the owners of the copyright (a German firm) in a manner scarcely less extravagant

than Sanatogen, and it was undoubtedly through the recommendations of physicians that it came to be classed as a patent medicine. Every physician knows that in a limited class of cases, with a correct diagnosis and other proper treatment, hexamethylenamine is a most valuable drug; but he also knows that it would be the merest chance if a layman took it in a case in which it would prove of benefit. The end-result would be the same as with other patent medicines: patients would be dosing themselves with drugs which could not possibly do them any good, and would delay the securing of proper medical advice. It may be added that repeated examinations by the U. S. Government and others have shown that the preparations of hexamethylenamine made by American manufacturers are in every respect the equal of the German product and are sold at a fraction of the cost of the latter. So physicians, by using the German proprietary name, have not only contributed to the introduction of what has been classed as a patent medicine, but have unnecessarily contributed to making the United States still more dependent upon foreign nations for even the simplest drugs. Such instances are, however, not common, and now that the medical profession has realized that it is confronted with a proprietary medicine evil in the same way that the public is confronted with a patent medicine evil, it may be confidently hoped that such instances will become rarer.

CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA.

IN the issue of the JOURNAL for September 23, we commented editorially on the approaching sixth annual session of the Clinical Congress of Surgeons of North America, to be held in Boston during the week beginning October 25, 1915, and spoke particularly of the series of meetings arranged for the first four evenings of that week. The complete program of these evening meetings has just been issued, and we desire to call it particularly to the attention of the profession.

On the evening of Monday, October 25, there will be first an address of welcome by Dr. Fred Bates Lund of Boston, chairman of the committee of arrangements, followed by the presentation of President William L. Rodman and President-elect Rupert Blue of the American Medical Association. Dr. John B. Murphy of

¹ From Nostrums and Quackery, published by the American Medical Association.

Chicago, the retiring president of the Congress, will deliver an address which will be followed by the inauguration of Dr. Charles H. Mayo as president and Drs. Herbert A. Bruce and Robert L. Dickinson as vice-presidents of the Congress. The exercises will be closed by Dr. Mayo's presidential address.

On the evening of Tuesday, October 26, the following will be the program of papers:—

Thomas B. Hartzell, M.D., Minneapolis: The Dental Path, Its Importance as an Avenue of Infection.

E. H. Sanford, M.D., Rochester, Minnesota: Studies in the Relationship of Amebiasis to Pyorrhea Alveolaris.

Weston A. Price, M.D., Cleveland: Cinematographic film showing movement of bacteria and amebae.

M. L. Rhein, M.D., New York City: Discussion.

George W. Crile, M.D., Cleveland: Acidosis in Its Relation to Surgery.

Professor Lawrence J. Henderson, Boston: The Nature of Acidosis.

James S. Stone, M.D., Boston. Discussion.

On the evening of Wednesday, October 27, the program of papers will be as follows:—

A. J. Ochsner, M.D., Chicago: Intestinal Stasis and Its Accompanying So-called Toxemia. Discussion by John G. Clark, M.D., Philadelphia; Professor Walter B. Cannon, Boston; Frank W. Smithies, M.D., Chicago.

Symposium: Plastic Bone Surgery (Illustrated by lantern). Fred H. Albee, M.D., New York City; Harry M. Sherman, M.D., San Francisco; John B. Murphy, M.D., Chicago; Charles L. Seudder, M.D., Boston.

On the evening of Thursday, October 28, there will be a symposium on cancer, the speakers on which are still to be announced; and a symposium on military surgery by Dr. George W. Crile of Cleveland, Dr. Harvey Cushing, Dr. Robert B. Greenough, Dr. Edward H. Nichols, and Dr. Robert B. Osgood of Boston.

This program promises a series of exercises of unusual interest and value in addition to the clinical meetings occupying the days,—a program deserving the attention of every practicing surgeon. Owing to the necessary limit of space and accommodation, however, it is impossible that these evening meetings should be thrown open to the profession at large and, therefore, only those who have registered as members of the Congress can be admitted.

ETHER DAY.

THE annual recurrence of Ether Day, which will be observed as usual at the Massachusetts General Hospital on Saturday of this week, October 16, recalls the story of the original demonstration of ether as an anesthetic in the old dome on that day in 1846. It is believed that the last remaining survivor* of those present on that occasion is Dr. Rufus C. Chapman, a dentist of Newcastle, Me. At that time Dr. Chapman had just begun the practice of his profession at Lynn and was fortunate in obtaining an opportunity to be present at Dr. Morton's demonstration. The events of that momentous morning are so familiar that the narrative needs no repetition. With each return of this anniversary, however, it must be realized that this event of such moment in the history of medicine and of the human race, is steadily passing into more remote time, and that already it is almost beyond the immediate recollection of those still living. The annual observance of this occasion, therefore, becomes of increasing importance, since it serves to prevent the oblivion of the immediate incidents and of the persons concerned in the first demonstration of ether anesthesia. It should be the interest and pleasure of every physician who can do so, to attend the morning exercises at the Massachusetts General Hospital next Saturday, of which the program is printed on the last page of this issue of the JOURNAL. The afternoon exercises are to be of the usual commemorative character, with a leading address by Dr. William W. Keen of Philadelphia. It is expected that this address will be published in full in a later issue of the JOURNAL.

MEDICAL NOTES.

DOG MUZZLING REDUCES RABIES IN NEW YORK.—Twelve hundred negligent dog owners were summoned to court during September by patrolmen of the Health Squad for failure to comply with the dog muzzling ordinance. Of these, only 112 were discharged; 832 paid fines, aggregating \$1034.

Naturally, the Department is much gratified at the strong support this ordinance has received at the hands of the city magistrates. That the enforcement of the law has been beneficial to the people of this city is indicated by figures concerning rabies and dog bites. Thus the number of cases of rabies found in animals examined in the Health Department's laboratories decreased from 64 in the second quarter of 1914 to 15 during the corresponding quarter of this year. During the same period a considerable reduction

* Since this was in press we have learned that Dr. Chapman died on Aug. 6, 1912, at the age of 90 years.

was also observed in the number of persons examined for dog bite.

WAR RAISES NEW YORK'S DEATH RATE.—An analysis of the mortality figures compiled by the Department of Health shows that during the past week, there were 77 more deaths reported than during the corresponding week of last year. Over forty of these, however, are accounted for by the increase of the city's population.

The diseases principally responsible for this increased mortality were diarrheal diseases, particularly under five years of age, whooping cough, heart disease and pulmonary tuberculosis. On the other hand, measles, diphtheria, bronchitis and broncho-pneumonia and diseases of the nervous system showed a decrease.

The total number of deaths reported during the week was 1209, with a rate of 10.86 as compared with 1132 deaths and a rate of 10.58 for the corresponding week of last year. The rate for the first forty weeks of 1915 is 13.37, as compared with 13.81 for the first forty weeks of 1914. According to the statisticians of the Department of Health, the death rate of the city has unquestionably been affected by the change in immigration and emigration that has occurred during the past year as the result of the European War, particularly as the city has lost large numbers of individuals between the ages of 15 to 40 years, *i.e.* at the age period when the death rate is the lowest.

The effect of the war upon municipal vital statistics is also reflected in a report of the city of Hamburg for March, 1915, which has just reached the Department of Health. In that city there was a falling off of 210 marriages during the month, as compared with the previous March, and a difference of 2.2 in the marriage rate. The Hamburg birth rate for March, 1915, was 2.6 lower than the average for the previous ten years.

PREVALENCE OF MENINGITIS, PELLAGRA, POLIO-MYELITIS, SMALLPOX AND TYPHOID FEVER.—The weekly report of the United States Public Health Service for Sept. 24 states that during the month of August, 1915, there were in Ohio 20 cases of cerebro-spinal meningitis, 100 of poliomyelitis, 91 of smallpox, and 581 of typhoid fever. During the same period, there were in Maryland 23 cases of poliomyelitis and 555 of typhoid fever. In South Carolina there were 66 cases of pellagra and 250 of typhoid. There were 50 new cases of pellagra in Nashville, Tenn., during the week ended September 4.

FOOT AND MOUTH DISEASE IN CHICAGO.—Report from Chicago on October 4, states that foot and mouth disease has recurred in one of the large herds in the local cattle yards. 170 animals were slaughtered on that day in an effort to check the infection.

NEW YORK RADIUM INSTITUTE.—Report from New York states that on October 5, contracts

were made in that city for the purchase of \$120,000 of radium for the New York Radium Institute which is to be established on 72nd Street in that city. This institute will devote itself to the philanthropic treatment of cancer and other diseases for which radium may be a therapeutic agent, on the analogy of the radium institute of London.

A NEW SOCIETY FOR THE CONTROL OF FEEBLE-MINDEDNESS.—There has recently been formed a society interested in the care and the control of the feeble-minded, calling itself "The Committee on Provision for the Feeble-minded" and expressing its purpose to be "to disseminate knowledge concerning the extent and menace of feeble-mindedness and to suggest and initiate methods for its control and ultimate eradication from the American people." The membership of the society includes members of State boards and commissions from five States—Indiana, Pennsylvania, Massachusetts, New Jersey, Virginia; superintendents and board members of institutions for the feeble-minded in New York, Ohio, Pennsylvania, Massachusetts, New Jersey and Minnesota; representatives of the National Committee for Mental Hygiene, the Eugenics Record Office, the Wistar Institute of Anatomy of Pennsylvania, the Vineland Laboratories, Johns Hopkins University and Stanford University; Judges of Juvenile Courts from New York and New Jersey; and others who have been prominent in doing or supporting social welfare work.

The executive work of the committee will be in the hands of Mr. Joseph P. Byers, formerly Commissioner of Charities and Correction of the State of New Jersey. Mr. Alexander Johnson, the former Director of the Extension Department at Vineland, now merged into the Committee on Provision, has become the field secretary of the new organization. The committee includes: Dr. Walter E. Fernald, Superintendent of the School for Feeble Minded at Waverley, Mass. The work of the Committee on Provision is being financed by private subscriptions from those interested.

YELLOW FEVER AT PANAMA.—Report from Panama on October 5, states that a death from yellow fever occurred on that day at the Ancon Hospital. This is the first case of the disease which has occurred in the canal zone for nearly eight years.

BOSTON QUARANTINE STATION.—On October 4, a conference was held in Boston between Dr. L. E. Cofer, assistant surgeon general of the United States Public Health Service, Dr. Allan J. McLaughlin, Massachusetts State Health Commissioner, Dr. F. X. Mahoney, Boston Health Commissioner, Dr. S. B. Grubbs, federal quarantine officer of the port of Boston, Mayor Curley and others, to determine the purchase price which the National Government shall pay to the city for the quarantine station on Gallop's Island. It is estimated the total cost will be \$250,000.

CANCER CONTROL IN MISSOURI.—The Department of Preventive Medicine of the University of Missouri, Columbia, Mo., has recently issued a special cancer bulletin (Medical Series No. 9) containing an article by Dr. F. A. Martin, instructor in pathology, on the early diagnosis and treatment of the disease. The purpose of the bulletin is to call the attention of the public to the work in popular education about cancer which is being done by the American Society for the Control of Cancer, by the American Medical Association, and by other national and state organizations. The importance of early surgical consultation is strongly emphasized and the attention of the public is directed towards the common early symptoms and signs of cancerous disease in various parts of the body. The bulletin closes with an emphatic warning against quacks and their spurious testimonials, pointing out that their method of deception is based chiefly on erroneous diagnosis.

LONG ISLAND COLLEGE HOSPITAL.—The fifty-seventh annual session of the Long Island College Hospital Medical School was opened at the Polhemus Memorial Clinic on Tuesday, September 28. The principal address on this occasion was delivered by Dr. Horace David Arnold, dean of the Graduate School of Medicine of Harvard University.

CONTAMINATION OF CLOTHING THROUGH PUBLIC LAUNDRIES.—Among matters of public health which are arousing interest at this time, the question of the possibility of infection through public laundries is receiving attention. Dr. Deeder of the committee on occupational diseases of the woman's department, National Civic Federation, reports in *Public Health* the results of his investigation of various laundries in New York. He considers the danger of infection to be, first to the employees of the laundry from soiled clothing and second, the contamination of the clean clothing with the soiled. The clean clothing which has been washed in boiling water and passed through the mangles at about 300° temperature may be considered sterilized but the conditions have been found very faulty in protecting this clothing from the soiled clothing taken into the laundry. In the majority of laundries it has been found that the clean clothes are manipulated in the same rooms with soiled ones, and often in close proximity, and the same table is used in places for receiving and delivery.

In France the matter has received much attention. Formerly the great washhouse boats were a feature of Seine scenery in and near Paris. They were an ancient institution, dating from 1623, but in 1885 were so numerous that contamination of the river from them was feared and they were prohibited. In 1905 the French Government made rules for the country which included impermeable bags for reception at the house and transportation of the soiled linen, disinfection before being handled by the workers, gowns for the workers like those in infectious hos-

pitals, washing of hands and face, separation of receiving and delivery rooms, prohibition of eating in the sorting rooms and vaccination certificates for the employees.

HEALTH OF SAILORS IN THE BRITISH NAVY.—There have recently been published figures which show that the percentage of sickness among sailors in the Royal Navy of England from 1902 to 1912 has decreased 10%. The mortality rate has fallen from 5.9 to 3.3. The improvement is accorded to general advance in education, the increased ventilation of ships and the institution of lectures on health.

CONSANGUINITY IN RAT BREEDING.—A press report from Philadelphia on September 29, describes recent researches by Dr. King at the Wistar Institute of Anatomy and Biology at the University of Pennsylvania in the breeding of rats, especially with reference to the effect of consanguinity. Dr. King is quoted as follows:

"In-breeding, corresponding to intermarriage in the human family, does not result in injurious effects. On the contrary, we have developed a type 30% larger physically by disregarding consanguinity.

"For 20 generations I have intermarried a brother and sister rat, with the result that I got a rat larger and better physically in every way than the first ones. A rat is a mammal and man is a mammal; therefore, it is not too much to think that the same principle can be applicable to each.

"I firmly believe that if close relatives, carefully selected and of a higher type, were to marry, the result of the union would be a higher type of offspring than from the intermarriage of two other people. The opinion regarding the degeneracy of the offspring of such a union exists because the only races who intermarry are degenerate races, and therefore, you get a race of even greater degeneracy."

As a matter of fact the traditional prohibition of consanguinity in intermarriage is presumably dependent on the greater likelihood in such marriages of intensifying a common family trait. The rapidity with which such traits may become intensified is likely to carry even an advantageous trait to such excess that it becomes disadvantageous by reason of its over-emphasis.

A subsequent press report quotes a comment upon this work of Dr. King by Dr. William Ernest Castle, professor of zoology at Harvard University. Dr. Castle has also experimented in rat breeding for a number of years and states as his experience, that with in-breeding, the progeny after a few generations becomes in most instances inferior. Of the application of such experiments to human beings, he is quoted as saying:

"A careful study of statistics obtained in cases where close blood relations have intermarried has shown that there has been a physical

and mental loss in the offspring. There are sound eugenic reasons why first cousins should not marry if the best physical and mental beings are to be produced.

"It certainly would not be justifiable to say that if in the interbreeding of rats healthy specimens are produced, the same reasoning can be applied in the breeding of human beings. Experiments and tests do not justify it."

ERADICATION OF HOOKWORM DISEASE.—The first part of the annual report of the Rockefeller Foundation issued in New York on September 23, describes the work of its international health commission up to the close of 1914 in investigation and eradication of the hookworm disease. After its initial work in the United States the commission undertook two further tasks: first, the extension to other countries of the work of eradicating hookworm disease as opportunity should offer and second, the following up of its treatment and cure through the establishment of agencies for the promotion of public sanitation and the spread of knowledge of the science of medicine.

"The relief and control of the disease is an undertaking of enormous magnitude, as the infection belts the globe in a zone on both sides of the equator, 66 degrees wide and with a population of about 900,000,000.

"Thus far plans have been adopted and work begun for the control of the disease in British Guiana, Antigua, Trinidad, St. Lucia, Grenada and Egypt.

"In addition to the work undertaken in the British colonies, the commission has responded favorably to invitations from several Central American countries and work has been inaugurated in Panama, Nicaragua, Costa Rica and Guatemala.

"The report makes it clear that the international health commission has not undertaken to eradicate the disease in any country. The accomplishment of this result, it is stated, will require the operation of permanent agencies working over long periods, and this should be the work of the governments interested. The commission's sphere of service, it is stated, is to cooperate with governments of foreign countries in organizing and making effective their own agencies.

"In this spirit, the report says, the commission has accepted the invitation of 11 foreign countries during the year to cooperate in the relief and control of the disease.

"In addition to carrying on its work in foreign countries, the international health commission has also undertaken to complete the program of the Rockefeller sanitary commission for the eradication of the hook worm disease in the southern states. This program, the report states, did not contemplate complete eradication under the supervision of the sanitary commission, but aimed rather at a comprehensive demonstration in each state, first of the presence of the disease, and

second, of the method of treating and preventing it. This demonstration is now entering its final stage with the inauguration of the so-called intensive community work, by which, in a limited number of typical communities in each state, it is hoped to show convincingly the possibility of treating every infected person, and at the same time of preventing soil pollution—the only way of preventing the recurrence of the disease.

"In concluding the report, the point is emphasized that the whole of the commission's work is essentially educational, and that its best result is in securing the cooperation of the people in the work of bringing this disease and all other preventable diseases under control."

EUROPEAN WAR NOTES.

APPOINTMENT OF DR. PENHALLOW.—It is announced in a report from London on Oct. 1 that Dr. Dunlap Pearee Penhallow of Boston has been appointed chief surgeon of the American Women's War Hospital at Paignton, South Devon, England, to succeed Dr. Howard Beal. The assistant surgeon will be Dr. Fred C. Coller of Boston.

CHOLERA IN AUSTRIA AND GERMANY.—During the week ended August 7, there were eleven cases and five deaths of Asiatic cholera at Trieste, Austria. During the same week there were in Germany 154 cases and 40 deaths of cholera and 2 cases of typhus fever. The majority of the cholera cases were among prisoners of war. The two patients with typhus were German soldiers, one at Breslau and one in Interfranken, Bavaria. Other cases of typhus occurred during the same period among prisoners of war in Königsberg, Lunenburg, Potsdam, Schleswig and Baden.

In the issue of the *Lancet* for Sept. 18 is the following statement of the prevalence of Asiatic cholera in Europe during the past year:—

"From information which we have obtained it appears that, since last September up to the present time, some 20,000 cases of cholera have been reported in the Austrian Empire, about a third of them proving fatal, and of these the largest proportion have occurred in Galicia and Bukowina, in the area in which military operations on a large scale are now being carried out. At first the disease made its appearance among the prisoners interned, but of late the majority of the cases have been recorded among the civil population. In the month of July of this year 6000 attacks occurred, mostly civilians, in the two above-named provinces. In Hungary more than 3000 cases have come under notice, principally among the military; and in Croatia-Slavonia about 1700 persons have been attacked. In Bosnia and Herzegovina there have been about 700 cases this year. The strain of infection, however, does not seem to be of a particularly virulent kind, and this lends confirmation to the opinion that Austria received the disease

from Southern Russia, where of late years cholera has been prevalent in a mild form. Sick and wounded soldiers from the battlefields of Galicia carried the infection back with them to various other parts of the Austrian Empire, and groups of cases developed in Vienna, Budapest, and other large cities. In the same way cholera was brought by Russian prisoners into Germany, the first cases being reported in November of last year in the Berlin district. This year, in July, there was a marked increase in the number of cases in Germany, and in the last week of that month 215 attacks were recorded, 200 of them among interned prisoners and only 15 among the soldiers guarding them. Cholera has also appeared at Frankfurt-on-Main and at various places in the provinces of Hesse-Nassau, Prussian Silesia, Posen, and Pomerania, as also in the kingdoms of Saxony and Württemberg. As might have been expected from what we know of German methods, anti-cholera inoculation has been largely used to protect the army fighting in the eastern war zone; the cases reported among the German soldiers being older men and those less fitted for active service, who were engaged in the less laborious task of guarding the prisoners' camps and who had not been inoculated. The anti-cholera inoculation no doubt accounts for the comparative absence of the disease from the German army in the field. This protective measure has also been employed by the Austrians, but probably less efficiently. In this connection it is of interest to learn that, although the inoculation was ordered to be carried out in the Austrian force about to be led against the Serbians, the general in command alone, of all his staff, refused to submit to the operation, and it is reported that he was the only soldier of that force who had so far died from cholera. Little definite information has come to hand from Russia as to the incidence of cholera of late in that country, but the fact that Russian prisoners conveyed the disease to Austria and Germany is evidence that it, too, has suffered. It is known, however, that just before war broke out last year cholera was prevalent in the Russian government of Podolia, not far from the Austrian frontier, and also that cases had occurred in Warsaw. During the present year it has been officially announced that the disease was present during August in the district of Kherson, not far from the Black Sea, and also Tiflis and other places in the Caucasus. As regards Turkey, we know that cholera was present during part of 1914 at Adrianople, Constantinople, and in the Dardanelles, at Gallipoli and Tschanak among the Turkish troops. At Smyrna, Trebizond, and other ports of Asia Minor cases were also reported last year, but there is no information available concerning the incidence of cholera in Turkey during 1915. Quite recently the disease has reached Italy, cases having occurred at Venice and Leghorn, probably due to infection from an Austrian source. So far as we know, there have been no

reported cases of cholera in the war zone in Western Europe. Although under different circumstances the presence of epidemic cholera in Eastern Europe might have caused some uneasiness in this country, the present danger may be regarded as comparatively insignificant, for the ports of Northern Europe, such as Libau and Hamburg, at which poorer class travellers from Russia embark for England, are closed; and the same applies generally as regards Austrian and Turkish travellers, to the corresponding ports in the Mediterranean. The season, too, is getting late, for cholera infection brought to our shores late in the year has in the past failed to effect a lodgment."

A YEAR'S RED CROSS WORK.—Mr. Sherman M. Craiger has recently published in the daily press a review of the work accomplished by the American Red Cross in Europe from the outbreak of the war until the withdrawal of its units on Oct. 1.

"The American Red Cross, at the outbreak of the war in August, 1914, tendered to the different countries involved the services of surgeons and nurses, together with supplies and equipment for hospitals, including outfits for sterilization. The offer was gratefully accepted, whereupon Congress consented to pass an act authorizing the society to take over a ship, under our own registry and flag. In answer to an appeal made in the press came the proffer of a Hamburg-American steamer, and it was accepted and chartered as the 'Red Cross' relief ship. Preparations were hurriedly made for its officering and fitting out, \$10,000 worth of absorbent cotton, gauze and other supplies being taken aboard at New York.

"As illustrative of the thoroughness of the society's organizations and methods, sixty of the nurses and surgeons, comprising Units D and E, were landed in England, as originally planned, at the end of September.

"Under Miss Lucy Minnigrode, as supervisor, the nurses for Russia, comprising Unit C, journeyed by train to London and Dundee, sailing from the latter point Oct. 2 for Bergen, and going thence to Stockholm and Petrograd by rail.

"From Portsmouth, England, the Red Cross landed the nurses in Units A and B in France, as well as the supplies for the American Ambulance Hospital in Paris.

"On Oct. 10 the sections for Germany and Austria were put ashore at Rotterdam, and traveled by rail via Berlin. Unit G, which was ordered to Kosel, in German Silesia, was in charge of Dr. Bial F. Bradbury, who was given a hospital building accommodating 100, with a first-class operating room.

"From Berlin the nurses for Austria were ordered to Vienna and Budapest, respectively, the former receiving Unit K, under the direction of Dr. Cary A. Snoddy, and the latter Unit E, with Dr. Charles E. MacDonald in charge.

"The Serbian unit of fifteen persons left New York on a Greek steamer.

"To send these 171 surgeons and nurses abroad, with adequate equipment, uniforms and other necessities; to pay their traveling expenses by land and sea both in this country and Europe, including salaries of \$60 a month for the nurses and \$166 to \$250 for the surgeons; and to bring them home to the United States at the end of six months, cost about \$1200 per capita, including the cost of the *Red Cross*, the relief ship on which they sailed, a total of \$205,000.

"Some conception of the stupendous amount of work done from then on may be gained from the following summary of services rendered to each belligerent Government:—

	SHIPMENTS.	VALUE.
Austria	11	\$97,683
Belgium	12	96,708
England	13	\$7,845
France	24	216,155
Germany	8	182,795
Italy	2	14,451
Montenegro	3	15,526
Poland	1	7,200
Russia	9	\$9,613
Serbia	8	130,867
Turkey	2	12,536

"In speaking of the cargoes sent, Miss Mabel T. Boardman, chairman of the National Relief Board of the American Red Cross, said that almost every conceivable thing which could give comfort to the sick and wounded had been donated to the society.

"For example, over 10,000,000 cigarettes reached us for the Allies and German-Austrian armies.

"More than a million yards of gauze have been contributed, 211,000 hospital uniforms, over a million surgical dressings, 31,000 pounds of anesthetic, \$92,000 pounds of cotton, absorbent and otherwise, 209,000 articles of clothing for refugees, 70 cases of typhoid and tetanus antitoxin, 10,000 smallpox vaccine tubes, 20,000 mufflers and 28,000 pairs of socks.

"Money was donated for the sanitary commission which went into the Balkan States to fight typhus. We purchased and shipped great quantities of supplies for them, including 358,000 pounds of sulphur, 700,000 bichloride tablets, 7000 gallons of kerosene to use in spraying for the destruction of typhus-carrying vermin, 5600 pounds of formaldehyde, 12,200 doses of cholera vaccine, 500 whitewash brushes, 3000 rolls of ribbon paper to be used in pasting windows to make rooms air-tight for fumigation, hundreds of barrels of old flour for making paste, many spray pumps, 35,000 gallons of phinotas oil, 70 bathtubs, 50 step-ladders and 11 automobile trucks.

"Of the designated funds which we have distributed, those to be sent to and spent in and for Germany have been in excess of all others. My estimate is that the Germans in this country have given not less than two millions direct for

relief in their Fatherland, and in one respect this must be classed as an American contribution.

"We have spent over a million dollars in actual cash for Belgium, and about half as much more for the other fighting nations in Europe."

"In the sure knowledge that a maximum amount of good has been accomplished with the means at its command, the Red Cross, at this writing, is preparing to recall the American personnel in Europe. On Aug. 25 three nurses arrived here from Kiev, Russia, where they had served practically a year, twice their enlisted term. Fourteen other detachments sailed for home during September, and it is expected that by the middle of October only two of our units of surgeons and nurses will be left to represent the American Society in the Old World. They are stationed in Belgium, where the need is of the greatest, and will be continued as long as funds are available."

WAR RELIEF FUNDS.—On Oct. 9 the totals of the principal New England relief funds for the European war reached the following amounts:

Belgian Fund	\$274,061.10
St. George's Fund	45,674.19
Surgical Dressing Fund	1,805.00
Red Cross Fund	1,362.58
War Children's Fund	347.50

BOSTON AND NEW ENGLAND.

BEQUESTS FOR CANCER RESEARCH.—It is announced that a bequest of \$25,000 has been given to the cancer commission of Harvard College by will of the late William Endicott. Another bequest of \$23,250, from the estate of Julia M. Moselet, has been made for the work of the cancer commission in the city of Boston.

EXAMINATION FOR MENTAL DEFICIENCY IN STATE PRISON.—The State Board of Insanity, at the request of the Massachusetts Prison Commission, has undertaken a psychiatric and psychological investigation at the Massachusetts State Prison in Charlestown with the purpose of determining the number of psychotic and defective individuals at present confined in the institution, and the results obtained from examination of the first group of criminals is published in the latest report of the State Board of Insanity (Bulletin No. 13, September, 1915). The report states as follows:—

"The object of the psychological study is to determine the intellectual status of the subjects, and to discover, if possible, mental reactions characteristic of criminal and delinquent individuals. To determine the intellectual status, the Yerkes-Bridges Point Scale (devised at the Psychopathic Hospital by Dr. R. M. Yerkes and J. W. Bridges) is used, supplemented by the Binet-Simon Scale when diagnosis by the Point Scale is uncertain.

"The diagnosis of mental deficiency, or feeble-mindedness, is made on the basis of a positive history and a low intellectual grading. No subject is diagnosed feeble-minded unless he grades below twelve years' mental age by the Point Scale. By using the twelve-year Point Scale age as the border line for feeble-mindedness, instead of the twelve-year Binet age, which is the standard limit commonly accepted, we ensure a diagnosis free from error, as it has already been proved that a subject who grades twelve years by the Point Scale must grade eleven or less by the Binet Scale. In our diagnosis of feeble-mindedness, we have followed the standard that a subject who grades between eight and twelve years is classified as a moron, and a subject who grades between three and seven years is classified as an imbecile.

"By the end of July, 1915, 100 cases had already been examined by Dr. Stearns, following the alphabetical order in which the inmates are catalogued at the prison. Of this group, 47 were given a psychological examination, because their social, criminal and medical histories were found to be suggestive of mental deficiency.

"Twenty-three of the 47 cases have been diagnosed as feeble-minded and 5 as border-line cases. Of the 23 feeble-minded cases, 2 fall in the imbecile group, 8 are classified as low-grade morons and 13 as high-grade morons. All of these 23 defective subjects are committable cases to institutions for the feeble-minded.

"A further, intensive psychological study is to be made on the inmates of the State Prison with the hope of finding characteristic reactions of the criminal and delinquent individuals, and a comprehensive report of the psychological findings will be prepared in the course of a year, after the study of all the inmates of the institution has been completed."

Massachusetts Medical Society.

ABOLITION OF WRITTEN EXAMINATIONS.

At a special meeting of the Supervising Censors, held October 6, 1915, it was voted in accordance with the authority conferred by Chapter V, Section 1, of the by-laws, that the written examination previously required of applicants for fellowship in the Society, be abolished. The suggestion marked No. 3, of the special committee appointed by the Supervisors at their annual meeting in 1914, and published in the JOURNAL, June 24, 1915, page 952, was adopted by vote. It is as follows:—

"3. Abolition of written examination; and reliance on the attainment of a degree from a school recognized by the Society, and the passing of the State Board as presumptive evidence of preliminary training; with reliance on the oral examination by the Censors to check up any doubts in individual cases, the chief function of

the Censors being to determine whether or not the candidate gives evidence through his record and his general bearing that he is desirable as a member."

It was voted further that the committee appointed last June be requested to prepare a set of examination papers that may aid the censors in conducting the oral examinations.

Voted by the Council, October 6, 1915. That the Librarian be instructed, until otherwise ordered, to furnish the business manager of the BOSTON MEDICAL AND SURGICAL JOURNAL by December first of each year, with the number of members of the Society entitled to receive the JOURNAL on March 1 of that year, and that that number be considered the minimum number of journals to be paid for by the Society in each respective year.

Voted: That the next annual meeting of the Massachusetts Medical Society shall be held in Boston, June 6 and 7, 1916.

(Signed) W. L. BURRAGE, M.D.,
Secretary.

October 7, 1915.

Miscellany.

PATENT MEDICINE PROSECUTIONS.

IN another column of this issue of the JOURNAL we have commented editorially on certain aspects of the patent medicine problem in its relation to the daily newspapers. It is interesting in this connection to note that two bills of information have recently been filed in the United States District Court by the local United States District Attorney, one against the Lydia E. Pinkham Medicine Company of Lynn on the charge of violation of the pure food and drug act, and one against J. M. Grosvenor and Company for similar violation in the shipment of Bell-Cap-Sie plasters. In the former bill it is alleged that a shipment of a dozen bottles of the Pinkham Vegetable Compound was fraudulently labeled as to medicinal properties.

The United States Department of Agriculture has recently issued a statement of over 50 legal actions which it has successfully terminated against patent medicine manufacturers for fraudulent claims as to the curative powers of their products. These actions have been conducted under the Shirley Amendment to the food and drugs act, which prohibits false and fraudulent claims as to the curative or therapeutic effects of drugs or medicines.

"Criminal prosecutions against the manufacturers were brought in 25 cases, but in 31 instances the falsely and fraudulently labeled medicines were seized while in interstate commerce. Claims made by the manufacturers for the curative powers of these preparations ranged from tuberculosis, smallpox and diphtheria, to coughs, colds and scalp diseases. A number of other criminal prosecutions and seizures are pending in various Federal courts throughout

the United States because of alleged violations of the Shirley Amendment, similar to those which have already been tried. The officials charged with the enforcement of the Food and Drugs Act are of the opinion that the evils of the patent medicine business can be stopped only by the most drastic action.

It is pointed out that traffic in medicines for which false and fraudulent claims are made is not only an economic fraud of the worst kind, in that a worthless preparation that costs but a few cents is frequently sold for a dollar or more a bottle, but that health, and even life, is endangered by failure to secure the service of a physician in such serious diseases as tuberculosis, diphtheria, pneumonia and scarlet fever, until too late, because reliance may have been placed in the curative powers of some worthless preparation which is claimed to be a never-failing remedy. The deluded victim may not realize his danger until the disease has reached a stage too far advanced for even the ablest physicians to cope with it. Effective treatment depends in most cases on applying it during the early stages of the disease.

The Houchens Medicine Company, of Baltimore, Md., pleaded guilty to the charge that a preparation called "Family Physician" and shipped by them into interstate commerce, was falsely and fraudulently labeled. Among the many diseases for which this medicine was recommended by the manufacturers in statements appearing on the labels and accompanying circulars, were diphtheria, scarlet fever, typhoid fever, smallpox, bronchitis, neuralgia, croup and all diseases of the throat and lungs. The following quotations from the label, carton, or circular are interesting: "The Public is hereby assured that this is the Genuine and Original Family Physician. . . For fever you need not give anything else but this Medicine, it will keep the rash out itself. . . For cases of Small Pox take plenty and often—Use freely. Give no hot teas, just give the medicine and what pimples are under the skin will come out; the rest will be carried off by the medicine. . . Also a wonderful and positive remedy for dyspepsia, keeps measles out nicely, regulates the bowels without trouble, and by purifying the blood prevents your liability to disease."

Analysis of the product, which was claimed by the manufacturer to be effective in the treatment of so many virulent and contagious diseases, as well as a variety of minor ills, showed that it was a syrup containing 19.2% non-volatile matter, 8.9% alcohol, anise, and a vegetable cathartic drug. The Government, therefore, charged that the medicine did not contain ingredients or medicinal agents effective for the relief and cure of the diseases which it was claimed to cure. The court imposed a fine of \$75.

A plea of guilty was entered by H. A. Ingham and Company of Vergennes, Vt., to the charge that statements and claims as to curative powers of a product called "Dr. H. A. Ingham's Vege-

table Expectorant Nervine Pain Extractor" were false and fraudulent. An analysis of a sample of the product by the Bureau of Chemistry showed the same to contain alcohol, 86%; opium alkaloids, camphor, capsicum, and vegetable extractive matter. The Government, therefore, alleged that the medicine did not contain ingredients or medicinal agents effective, as the labels or circulars asserted, to subdue raging fever, or to cure typhoid fever, lung fever, scarlet fever, rheumatic fever, cholera, dysentery, sunstroke, diphtheria, bleeding at the lungs, nervous exhaustion, or piles, or to prevent fits of apoplexy and epilepsy when coming on, or to heal without inflammation or suffering all wounds, sprains, or burns, or to break up a felon, or to cure congestion of the lungs, pleurisy, fits of apoplexy, chronic rheumatism, paralyzed limbs, and croup.

It was also alleged by the Government that the statements "For teething and restless children, it is not only safe and harmless, but positively beneficial; it agrees with the most tender child or feeble infant," were false and misleading in that they were of such nature as to mislead the purchasers into the belief that the article contained no harmful or poisonous ingredient, whereas, in fact it did contain morphin and other opium alkaloids of a poisonous and deleterious nature, such as might prove harmful and deleterious to the health of tender children and feeble infants, and other persons, if consumed by them. The court fined the defendant \$100.

Four thousand and ninety-two bottles of "Father John's Medicine" were seized in Philadelphia, Pa., it being alleged in the libel that the labels on the bottles and on the pasteboard packages containing the bottles bore statements regarding the curative effects of the medicine that were false and fraudulent. Claims were made by the manufacturers for the efficacy of the medicine in the treatment of consumption, coughs, colds, croup, asthma, bronchitis, sore throat, whooping cough, pneumonia, catarrh, rickets, and a number of other ailments. A judgment of condemnation and forfeiture was entered, and it was ordered by the court that the product be delivered to Carleton and Hovey Company, Lowell, Mass., upon payment of all the costs in the proceedings and the execution of a bond in the sum of \$5,000, to insure that the goods would not be sold unless truthfully relabeled.

A verdict of "guilty" was rendered against the American Laboratories, a corporation located at Philadelphia, Pa., for shipping into interstate commerce a product called "Bad-Em Salz," which it was alleged was falsely and fraudulently labeled. An analysis of a sample of the product showed that it consisted of common salt, Glauber salt, baking soda, and a small amount of tartaric acid. It was claimed by the manufacturers that this preparation reproduces the medicinal properties of the great European springs famous for centuries for the cure of di-

eases of the stomach, intestines, liver, kidneys, or bladder, and that it represented the medicinal agents obtained by the evaporating of the water from famous European springs. The Government alleged, among other things, that these claims were false and misleading. It was also alleged that the statements in the circular indicating that the preparation contained ingredients or medicinal agents effective for dissolving gall-stones, for the prevention of gastritis, for curing diabetes, for preventing or checking chronic inflammation of the kidneys, and for relieving catarrh of the bladder, were false and fraudulent. A fine of \$100 was imposed by the court."

Correspondence.

A CHINESE AUTOPSY.

CHANGSHA, HUNAN, CHINA, August 29, 1915.

Mr. Editor: It may be of interest to your readers to hear a word about the first official autopsy ever performed in this section of China. The absolute refusal of the Chinese to permit post-mortem examination has been a major handicap in the development of western medical education and practice, as not alone were autopsies impossible but material for dissection was unavailable. The first real step of progress was the proclamation of the Board of the Interior of the central government at Peking in 1913 declaring that autopsies and post-mortem dissection for educational purposes were legalized. Thus, for the first time in China, post-mortem examination had legal sanction.

Following this in the chief open ports such as Hankow, Shanghai, Canton and also in Peking, post-mortem examinations were soon initiated. But in the interior popular superstition and prejudice are even yet proof against governmental mandates.

Changsha, the site of the Hunan Yale College of Medicine and Hospital, is the capital of a province inhabited by 22 million people. Changsha has been an open port for little more than a decade, and in fact the first foreigner penetrated within the Changsha city wall at the peril of his life less than fifteen years ago. With these bare facts in mind, it is worthy of remark that the first autopsy in Hunan has been performed. The conditions and surroundings were striking in the extreme.

A body was found on the street by the police, and as no relatives or friend could be found, the suspicion of foul play was entertained. A representative of the Commissioner of Police, therefore, waited on Dr. Yen, physician-in-charge of the Yale Hospital, and requested a medical certificate of the cause of death. A formal post-mortem examination was quickly arranged for the following morning at eight o'clock at the municipal poor house, east of the city wall.

Promptly at eight o'clock on Friday morning, the 20th of August, Dr. Yen, Dr. Young and myself arrived at the poor house. This is a large and excellently run institution where the indigent population is provided with work in weaving, basketry and other industries, under conduct of the police. A school is also maintained for poor children. After diligent inquiry we found that the suspected victim of foul play had been buried the night before. In fact the messenger of the Police Commissioner ordering the body held for autopsy, who should have arrived the afternoon before, arrived after we did. We determined at least to inspect the grave, so we headed a procession of police officials, beggars, farmers, coolies carrying instruments, basins, etc., out into the rolling grave-covered hills across the railroad east of the city wall.

It was a mid-August morning and the sun beat down through helmet and umbrella as only a Chinese sun can do. We held council on the grave and finally sent for a detachment of police and a crew of grave diggers. The body was exhumed, the heavy coffin lid laid across two granite tomb stones a thousand years old or more, formed a convenient table. Police, armed with bayoneted rifles formed a large circle. With punksticks burning about us and a coolie swinging a sprinkling can of disinfectant like a large censer, the work proceeded.

The cause of death was ascertained in all probability to be heat stroke superimposed upon an extreme fatty degeneration of the liver. Extensive specimens were secured and the body re-interred. The representative of the police then made an address explaining the importance of determining the cause of death in such cases and Dr. Yen followed with a statement of the need of such work for medical education. The coffin was then sealed with long strips of paper showing that it had been opened by court order. As we returned toward the east gate, we passed a huge poster on a mud wall, issued by the civil governor of Hunan Province at the request of the Commissioner of Police, authorizing the autopsy under the proclamation of 1913.

Thus was established in Hunan a precedent for autopsies and human dissection. Its value to the Hunan Yale College of Medicine can hardly be exaggerated.

Very truly yours,

ALFRED C. REED, M.D.

THE NATURE OF THE NEUROTIC.

SPRINGFIELD, MASS., September 30, 1915.

Mr. Editor: The reading, in today's JOURNAL, of your description of a new theory of the neurotic, by one Adler, a disciple of Freud, but apparently purged of Freudian filth, recalls the description of a proprietary article, where powdered clay masquerades in the verbiage of levigated anhydrous argillaceous mineral matter. But as some pith is always found among the sundry, divers as's and whereas's of a legal brief, so we are delighted to find among Adler's mingled "subnormal functions," "organic inferiorities," "defective activities," "self-maximizations," "full masculinities," etc., a recognition of the fundamental fact, long recognized by non-rainbow-chasers, that the neurotic is just a plain damn fool, of varying degree, sometimes permanently, sometimes temporarily, unable to control or withstand the multiple stimuli of life, be they endogenous or exogenous.

Very respectfully yours,

PHILIP KILROY, M.D.

NOTICE.

UNITED STATES NAVY MEDICAL CORPS.

The next examination will be held November 15, 1915, at Washington, D. C.; Boston, Mass.; New York, N. Y.; Philadelphia, Pa.; Norfolk, Va.; Charleston, S. C.; Great Lakes (Chicago), Ill.; Mare Island, Cal., and Puget Sound, Wash.

Applicants must be citizens of the United States, and must submit satisfactory evidence of preliminary education and medical education.

The first stage of the examination is for appointment as Assistant Surgeon in the Medical Reserve Corps and embraces the following subjects: (a) Anatomy, (b) physiology, (c) materia medica, (d) general medicine, (e) general surgery, and (f) obstetrics. The successful candidate then attends a course of instruction at the Naval Medical School, during which course he receives a salary of \$2000 per annum, with allowances for quarters, heat and light, and at the end of the course, if he successfully passes an examination in the subjects taught at the

school, he is commissioned an Assistant Surgeon in the navy.

Full information with regard to the physical and professional examinations may be obtained by addressing the Surgeon General of the Navy, Navy Department, Washington, D. C.

BELGIAN PHYSICIANS' RELIEF FUND.

REPORT OF THE TREASURER OF THE COMMITTEE OF AMERICAN PHYSICIANS FOR THE AID OF THE BELGIAN PROFESSION FOR THE WEEK ENDING OCTOBER 2, 1915.

No contributions for the week ending October 2, 1915.

Previously reported receipts.....\$7866.84
Total disbursements.....7310.04

Balance\$ 556.80

F. F. SIMPSON, M.D., *Treasurer*,

Pittsburg, Pa.

NOTICES.

MASSACHUSETTS GENERAL HOSPITAL.

Demonstrations in the Surgical Amphitheatre.
"Ether Day", October 16, 1915.

The demonstrations will be carried out on the time scheduled regardless of attendance.

1. DR. G. A. LELAND, JR. "Mobilization of the Knee in Cases of Fractured Femur." 10.00 A.M.
2. DR. F. G. BRIGHAM. "The Allen Treatment of Diabetes in the Out-Patient Department." 10.10 A.M.
3. DR. O. F. ROGERS, JR. "The Allen Treatment of Diabetes in the Wards." 10.20 A.M.
4. DR. C. J. WHITE. "Food as a Possible Etiological Factor in Eczema." 10.30 A.M.
5. DR. HUGH CABOT. "Demonstration of the Lesions Produced by Different Types of Kidney Infections." 10.40 A.M.
6. DR. W. E. PAUL. "Injuries to Peripheral Nerves." 10.55 A.M.
7. DR. C. A. PORTER. "The Results in Cases of Peripheral Nerve Surgery." 11.10 A.M.
8. DR. C. L. SCUDDER. "The Surgical Treatment of Chronic Duodenal and Gastric Ulcer." 11.25 A.M.
9. Operations by the Surgical and Special Services. 11.40 A.M. to 1 P.M.

The Out-Patient Department, Pathological Laboratory, Zander Room and X-Ray Department will be open for inspection.

ETHER DAY ADDRESS.

Members of the medical profession are invited to attend the Ether Day address by Dr. William Williams Keen, subject, "The Dangers of Ether as an Anesthetic," on October 16, 1915, at 4 P.M., to be held in the lower out-patient amphitheatre on Fruit Street, Massachusetts General Hospital.

HARVEY LECTURE.

The first lecture of the annual series of the Harvey Society will be delivered at the New York Academy of Medicine on October 16, by Professor Charles Wardell Stiles of the United States Hygienic Laboratory, Washington, D. C., on "Recent Studies on School Children with Special Reference to Hookworm Disease and Sanitation."

REPRINTS AND PAMPHLETS FOR THE SURGEON GENERAL'S LIBRARY.

In aid of completing the bibliographies of American physicians in the Library of the Surgeon General's Office, Washington, D. C., it is highly desirable that all reprints and pamphlets not saleable in the general

market should be deposited therein. Physicians who desire that their writings should be preserved in this collection will confer a benefit by sending copies of all separate pamphlets and reprints of their authorship, or bound collections of the same, to

The Librarian, Surgeon General's Office,
Army Medical Museum, Washington, D. C.

RESIGNATION.

Dr. Charles K. Mills has recently resigned, after a service of 22 years, as professor of neurology and psychiatry at the University of Pennsylvania.

APPOINTMENTS.

Dr. Edward C. Briggs of Harvard Medical School, upon his resignation as professor of materia medica, has been appointed by a vote of the Board of Overseers of Harvard, professor emeritus.

Dr. Hugh Barr Gray, of College Point, New York, has been appointed superintendent and resident physician of the Washingtonian Home, Boston, to succeed the late Dr. V. A. Elsworth.

Dr. James Craig Neel has been appointed instructor in obstetrics and gynecology at the University of California Medical School.

Dr. R. G. Pearce has been appointed assistant professor of physiology in the University of Illinois.

SOCIETY NOTICE.

NEW YORK AND NEW ENGLAND ASSOCIATION RAILWAY SURGEONS.—The twenty-fifth annual session of the New York and New England Association Railway Surgeons, celebrating the quarter century anniversary of the organization of the association, will be held at Hotel Astor, New York City, October 21, 1915, under the presidency of Dr. W. H. Marcy, of Buffalo, N. Y.

A very interesting and attractive program has been arranged. Railway surgeons, attorneys and officials, and all members of the medical profession are cordially invited to attend.

GEORGE CHAFFEE, M.D.,

Corresponding Secretary.

33S 47th Street, Brooklyn, N. Y.

RECENT DEATHS.

DR. F. FILMORE BURTIS, a surgeon of the steamship *Advance* of the Panama Railroad and Steamship Company, recently died on board the *Advance* and was buried at sea. He was born in 1877 at Troy, N. Y., where he received his education and graduated from the Medical College of Union University. He subsequently became city physician, coroner's physician, police physician and deputy coroner at Schenectady, N. Y. About five years ago he moved to New York and practised his profession in that city until his appointment to the *Advance*. Dr. Burtis was a member of the Schenectady Medical Association. He leaves a brother and two sisters. He was unmarried.

DR. CHARLES W. STILES, who died on Oct. 7, in Somerville, Mass., was born at Albany, Vt., in 1850. He received the degree of M.D. in 1888 from the Boston University School of Medicine. He had practised his profession in Newburyport, Allston, and Somerville. He was rhinologist at the Massachusetts Homeopathic Hospital, and a member of the National Institute of Homeopathy, the Massachusetts and Boston Homeopathic Medical Societies, and the Surgical and Gynecological Society.

Address.

THE RELATION OF THE MEDICAL PROFESSION TO PREVENTIVE MEDICINE.*

BY HAVEN EMERSON, M.D., NEW YORK.

THREE parties are concerned in the prevention of disease,—health department officials, the citizens as a whole, and the medical profession.

The officials are concerned with the administration of laws based upon the application of accepted facts to actual living conditions. They are bound to carry out the provisions of the sanitary code of state or town and to enforce other laws, whether federal, state or local, which apply to the protection of health and life.

Citizens are obliged under the law to abate nuisances, when notified. They must give notice of the presence of communicable diseases. They must refrain from any act and avoid permitting any conditions harmful to health. The citizen's complaint is, in a way, a measure of public opinion for or against conditions supposed to have some relation to health. He is entitled to protection from the ignorance or neglect of his neighbor. He cannot be trusted as a sanitarian to inspect or estimate the importance of conditions he is annoyed or endangered by. He can be educated to demand improved sanitary standards, and his capacity for education and his respect for law are the measures of the possibility of progress in preventive medicine, everywhere

except under military conditions, where the citizen has no choice but to obey.

As licensed to practise by the state or (it is to be hoped) in the future by the nation, practitioners of medicine bind themselves to observe and operate the laws. They are specified under various federal, state and local laws among other privileged professional groups as having certain duties and responsibilities in the matter of reporting births and deaths, notifying communicable diseases and occupational diseases or poisons, and in the use of drugs. They are the unofficial agents of the state and local health boards. Their contract with their consciences is expressed in their Hippocratic oath. Their contract with the state is expressed in the license to practise. Both informal and formal engagements bind the practising physician to heal the sick.

The citizen is helpless without his physician. The community accomplishes but little, and that little slowly, and wastefully of time and money, without its health officer. Health officer and physician are at disadvantage unless they recognize their respective fields and duties. The physician can no more do his full duty by his patient without the coöperation and assistance of the health officer than can the health officer serve the community unless the practitioner of medicine is his assistant.

The health officer is, or should be, a full time, suitably paid, qualified physician, a civil service appointee, and competing in no way with the practitioner of medicine. His function is to diminish the need of the practitioner as a therapist and to develop new and wider fields of

* Read at the meeting of the Harvard Medical Alumni Association, Boston, May 20, 1915.

usefulness for the practitioner as a diagnostician, and student of epidemiology, as analyst of personal and social and even economic disease, as educator of persons, groups and communities.

Treatment of disease should be no part of the functions of a Department of Health, except where existing facilities are lacking, and the burden is properly a community one, and the people concerned are too poor to pay.

In New York City we treat trachoma in the indigent, and remove tonsils and adenoids as other dispensaries and hospitals do, after the same kind of social investigation of each case as dispensaries are required to give. We re-educate school children who are too poor to go to oculists. We maintain diagnostic clinics for tuberculosis, syphilis, gonorrhea, and occupational diseases. We maintain hospitals and a sanatorium for tuberculosis, and hospitals for measles, diphtheria and scarlet fever. We provide accommodations under police power for such tuberculosis and syphilis patients as are a public menace, and decline to submit to treatment voluntarily, or to obey sanitary regulations.

We used to administer diphtheria antitoxin on request by physicians, because of dosage and procedure were unfamiliar to most physicians when diphtheria antitoxin was introduced. We discontinued it two years ago at the request of physicians who said the department was taking the bread out of their mouths. The increase of diphtheria in the past two years makes us suspect that the practitioners of medicine are not using antitoxin as promptly as necessary, or for immunizing doses as freely as was formerly our practice, and as is necessary to control the disease. We administer tetanus antitoxin by the intraspinal method at physicians' request, as the method is not universally understood and the dosage is often unsuitable when called for from our laboratories by physicians. We vaccinate as necessity arises. I think this completes the record of our services for the treatment of disease.

We find a very general failure throughout the city on the part of the public dispensaries to treat syphilis and gonorrhea effectively or, I may say, in a way warranted by our present knowledge of diagnostic and therapeutic possibilities. It seems quite possible that the only way of obtaining a higher standard of diagnosis and cure for these preventable notifiable diseases, will be to enter the field of therapeutics.

We have shortened the period of quarantine to conform to the results of exact studies in whooping cough, measles and scarlet fever. A measles patient is released five days after the appearance of the rash unless the physician in attendance decides to extend the quarantine because of the existence of infectious discharges from nose or ears or persistence of cough. This practice is based on the evidence produced by Anderson and Goldberger, which showed that measles was not transmissible in monkeys for more than three days after the appearance of the rash.

A whooping cough case is not quarantined

more than two weeks after the appearance of the whoop. This is based on the evidence of our own bacteriologists, who have been unable to isolate the specific microorganism from the sputum at a later date than two weeks after appearance of the whoop.

A case of scarlet fever is freed from quarantine 30 days after the appearance of the rash regardless of the incompleteness of desquamation, except when there is a persistence of discharges from nose, throat or ears. This is based on clinical experience within the department, and the fact that scales do not appear to be capable of conveying the disease.

Diphtheria is quarantined only until two successive negative cultures are obtained from nose and throat. We no longer demand fumigation of the premises after measles, diphtheria, scarlet fever and tuberculosis. We demand personal cleanliness during the course of the disease and thorough cleaning of premises with soap and water, followed by ample ventilation. The failure of gas fumigation to penetrate and the inefficiency of fumigation as a safeguard have led to this decision.

According to the grade of intelligence of the family and the character of medical and nursing services provided for the sick, we either merely observe the case at outset and make no further visits, or the case is kept under careful supervision during the communicable stage to prevent failure of personal quarantine.

We have carried on a persistent campaign in all classes of the community for universal annual medical examinations by competent physicians. We have undertaken studies of occupational diseases and have urged upon employers the necessity of employing a physician as a part of their force to study their employees, to guide their industries as far as physical welfare and fitness to work, hygienic conditions of employees at home and at work are concerned, and as a teacher of human efficiency.

Many physicians whose work has been limited to so-called old-fashioned regular family practice, have noted a falling off in their incomes. This is but natural in view of the marked reduction in preventable diseases and in the diseases of the first two decades.

To offset this, we are creating a demand for the services of physicians as diagnosticians and practitioners of preventive medicine among the healthy or but slightly afflicted, and we are developing a need for physicians as agents of the state, their services to be administered for the benefit of the whole community.

The community is not getting the benefit of more than a small fraction of the knowledge and skill available in the profession of medicine. It never will until some system of administration, either by voluntary coöperation or by compulsory organization, is developed which will provide services in proportion and of the kind needed by the community.

Voluntary coöperation is shown in its best

form by associates in medicine, surgery, and the specialists who work as a unit from joint offices, or as the staff of a community hospital; such groups of clinicians resembling in efficiency the medical board of a well organized public hospital.

Compulsory organization has been attained in England and with a large measure of success. Something better should grow from it, and it would not be strange if we saw some State insist upon obtaining for its often helpless and uninformed citizens, its quack-ridden foreign factory operatives, etc., the services of a group of state physicians serving the communities in proportion to their needs in kind and amount of services, and paid for by taxation for public health service.

I do not believe a State medical service is the inevitable solution. The profession has a wonderful opportunity, which it must grasp promptly, and handle in a way worthy of its past record of public service if it would avoid the charge of considering its own interests before that of its patients. The community respects the profession, it looks to it for the solution of most of its ills, it is ready to support all reasonable measures and expenses asked by the profession, but there is a strong feeling that few physicians are as interested in prevention as they are in treatment. This impression must be dissipated.

Constipation cannot be treated without a personal knowledge of the patient's habits of life. A diagnosis of valvular heart disease is of no use to the patient unless you know how many flights he climbs to get to work each day. Positive sputum and a pulmonary lesion, even verified by x-ray and followed by suitable advice to the tuberculous, does not express the full function of the physician. Are others in the same shop or house developing tuberculosis? Are you treating a person or a community disease, assisted by alcoholism, developed in poverty, infected in a neglected environment?

The medical adviser's work is only just begun when diagnosis and treatment are offered. Diagnosis is only fragmentary if it is merely anatomical. Does the oculist find out why the child with a moderate myopia at six is a severe sufferer at eleven? Has he visited the school, noted the faulty adjustment of seat and desk, light and size of type, and by his protest saved others from a similar misfortune?

Has the aurist followed his chronic otitis case to the fur shop and seen the environment in which the daily dose of hair particles develops the chronic catarrh of the nose and throat, which will determine a certain number of deaf workers, so many cases of bronchitis and asthma?

No! They leave those things to the Health Department. The people learn the cause of their defects through the Health Department, and their family practitioner might have told them first and become the adviser to a trade group as well as to an individual.

The Health Department should be the servant of the medical profession and the public. The physician should coöperate as an associate instructor, as a volunteer field agent for the Health Department. The citizens show every inclination to support liberally both groups, and they are learning that preventive medicine is as good an investment as fire insurance.

The Health Departments are supported by a moderate tax upon all, for community improvement. Individuals will as readily tax themselves, and more liberally, for personal betterment if they can have some assurance that the character of services is the best obtainable and will be maintained. No individual physician without unusual resources can command for his patients the service of supporting experts and special data necessary to arrive at a thorough opinion as to his patient's condition. It is not the simple matter of distinguishing by a culture, a blood count, an x-ray or a skin reaction between two or three possibilities, with the certainty that careful clinical observation and treatment applied with good judgment will give the patient relief. The problem is one of detection of as yet unsuspected early indications of susceptibilities, approaching deviation from the normal limits of individual variation, tendencies to degeneration, chronic diseases of nutrition, progressive departure from safety in various functions. To give an opinion to a healthy man that he is well and free from threatening infirmities, to warn and advise the one who begins to show the damage of worry and severe strains, to check the over-zealous, to warn the lazy of the penalties of atrophy, to safeguard the special senses against abuse,—these take a much higher grade of diagnostic skill, a greater degree of coöperation among physicians, variously skilled in specialties, than does the practise of medicine upon the sick.

Coöperation is fundamental. The beginner cannot go it alone, he must combine with his contemporaries, or be associated with his seniors, or obtain permanent opportunities to get laboratory and technical assistance to complete his own physical examination. Chemistry and physics have got too far in applied medical diagnosis to permit any man to be his own complete laboratory assistant.

Can there be any question that the consultations of the future will be studies of doubtful cases of health? The learned discussions over the terminal manifestations of a fatal illness will give way to interpretations of facts as presented by a patient in full bloom of youth or in sturdy middle age.

To accomplish this will demand of the physician that he continue to study and improve. We shall find the post-graduate school a necessity. The state will be justified in adopting the policy of the army medical staff and demand a qualifying medical examination, every five or ten years, as a requirement for continuance in practice, and not alone for admission to practice.

Once the public realizes the present tremendous per cent. of error in diagnosis, even under the best hospital conditions, and autopsies will be demanded, it is to my mind a close question whether the medical profession will feel more humbled or the layman more alarmed when universal and recorded autopsies exhibit the limits of medical capacity.

The opportunity is calling. The medical schools are graduating competent men, post-graduate instruction is available. Coöperation is necessary for efficient service to the public. Preventive medicine, as applied to the families under our care, is a necessity. Will you wait until the State demands that you practise under her control, or will you take the obvious course and meet with organization for diagnostic efficiency, the call of a public increasingly well informed and eager to be advised? Whether we wish it or not we are involved in a stern and stirring conflict, and we cannot do better than to remember President Hadley's words:—

"For, after all, the lesson which observation teaches to the man of brains is the same that instinct has taught the gentleman for many ages past,—that in any conflict which is worthy of the name, strength counts for less than intelligence, intelligence for less than discipline, discipline for less than self-sacrifice, or to put it in positive words, that unswerving devotion is the thing that counts for most of all."

THE SYPHILIS WE SEE BUT DO NOT RECOGNIZE, AND THE IMPORTANCE OF FAMILIAL STUDIES.*

BY HENRY FARNUM STOLL, M.D., HARTFORD, CONN.,

Assistant Attending Physician to the Hartford Hospital, Hartford, Conn.

SHORTLY after the establishment of a special clinic for the treatment of syphilis at the Hartford Dispensary I remarked to a medical colleague that we were prepared to treat any of his patients who might need salvarsan but who were unable to pay the usual charge for treatment as private cases. He thanked me for the information, adding that he rarely saw any cases of syphilis in his practice but that if he should run across any, he would remember us.

I refer to this conversation because it is typical of the reply the average physician would make and is exactly what I would have said under the same circumstances a few years ago. A definite case of syphilis that could be diagnosed by a third-year medical student is one thing and the individual with some obscure symptom or physical sign who appears in the consulting

room of the general practitioner rather than in that of the syphilographer, is a very different affair. Especially so if the patient be a man or a woman of eminent respectability, and the cases here reported we might meet in business, at the club or in any drawing-room.

I have purposely included several cases that were not correctly diagnosed until many months after they first came under my observation, as it is only by recognizing our mistakes, that we can hope to lessen their frequency.

CASE 1. A man of forty consulted me some four and a half years ago because of a cough which he had had for nine years. He was also weak and each morning for the past six months had a severe headache on awakening. His coughing spells were severe and the paroxysms so marked that at one time he fell from his wagon. Another time he was sitting at a table and he coughed so severely that he fell from his chair. He was an inveterate cigaret smoker, drank to excess, overate and under exercised. He had had much sour stomach and five years ago his appendix was removed. Each night he arises two to four times to pass his water. Recently he has been taking some headache medicine several times a day. His family history was not particularly remarkable. His mother died of "asthma", age fifty-three, she was subjected also to hard coughing spells. His wife is living and is somewhat of a "neurasthenic". She has five children and has had several criminal abortions. Twenty years ago, prior to his marriage, he had some insignificant venereal sore which was not followed by any secondaries.

He was a very large man, weighing 220 pounds, with a bluish tinge to his hands and lips. He had the "wheeze" of chronic bronchitis and emphysema and there were sibilant râles over both lungs.

The urine exhibited a trace of albumin from time to time and occasionally a few casts were seen. No tubercle bacilli were found in his sputum. The systolic blood pressure was 100. This was a surprise because the history of morning headaches and nocturia at once suggested hypertensive disease. Quite recently Volkhard¹ drew attention to the fact that syphilis not infrequently causes this picture, for which he has suggested the term "nephrosis." The diagnosis in this case was chronic bronchitis, emphysema, nicotine and coal tar poisoning. It also seemed probable that there was some cardiac and renal pathology. It was impossible to obtain the co-operation of the patient in regard to his vicious habits.

A small dose of sodium bromide and potassium iodide made him feel better. About eighteen months later he again came in complaining of very severe headaches during the night, especially in the early morning, and of some pain across the chest. He was smoking about three packages of cigarets a day and taking headache wafers. His lips were still blue. The systolic blood pressure was 135 and the urine contained a trace of albumin. At this time he drew my attention to a horny condition on the back of his hands near the knuckles. As this looked like a late skin syphilide, Wassermann and huetin tests were made and both were very positive. His headaches were of such severity that a lumbar puncture was done but except that the pressure was over 250 m.m. the fluid was negative. He received several injections of neosalvarsan and mercury and ulti-

* Read before the Tolland County Medical Society at Stafford Springs, Conn., October 19, 1915.

mately his headaches disappeared though they did not respond promptly. Had I thoroughly investigated the health of this man's family when I first saw him I might have made the correct diagnosis at that time rather than eighteen months later. His wife has been more or less constantly under medical care for nervousness and "dreadful headaches". The eldest son stutters very badly and eight years ago had "sore eyes" and at this time had an acute interstitial keratitis. A daughter of fourteen is very robust but has one short arm. Another daughter, age ten, is subjected to headaches. A third daughter of seven years also has a short arm. With one exception, all had either a positive Wassermann or luetin test.

This family illustrates the tragedy that may follow in the wake of an ante-marital infection and shows hereditary syphilis as an active disease and as a creator of dystrophies.

While it has long been known that headaches of acquired syphilis are rather more apt to be severe in the early morning, it is not generally appreciated, however, that hereditary syphilis may cause exactly the same sort of headache. Excluding headaches due to acquired syphilis, the eyes, kidneys and intestinal stasis, I believe the majority are due to a prenatal luetic infection. Many cases of migraine belong to this group. Many, perhaps most, of these individuals do not show any of the common stigmata of hereditary syphilis.

CASE 2. A young woman of twenty-four, married five months, complained bitterly of headaches. As a child she was very well but about six years ago she began to suffer from severe headaches. They would sometimes come on during the night and would be so severe that they would awaken her; they usually were somewhat better by noon. She has one sister who suffered so severely from headaches that she had to leave school. Many physicians were consulted but neither of the young women obtained relief. Her mother is living and appears to be in good health. There are two brothers and two sisters and the mother has had two miscarriages. Her husband has had no venereal disease.

The fact that the father had died at fifty from "shock" was the first thing to suggest the possibility of syphilis, as sudden death at that age is usually due to that cause.

This young woman was an exceedingly fine looking, healthy individual. She had excellent teeth and the only thing noted was the fact that her eyes were slightly prominent which, however, she informed me was normal for her. The Wassermann was very strongly positive. She was put on active treatment, potassium iodide and daily injections of mercury for the first two weeks, then salvarsan.

She received several injections of salvarsan, with ultimately marked relief but for the first week or ten days however, after the treatment was begun her headaches were definitely worse. This is a very significant fact as I have repeatedly observed headaches, joint pains, anginal pains, etc., made distinctly worse when specific treatment was first instituted. In fact, aggravation of the symptoms occurs so frequently that it is in a manner diagnostic and it is because prompt relief has not followed in many instances that specific treatment is often discon-

tinued before it has really been thoroughly tried out. Since putting this patient on specific treatment, the slight exophthalmos has become notably less.

A group of cases whose etiology is obscure and whose treatment is unsatisfactory comprises the patients who complain of an indefinite pain in the precordial region. This pain frequently seems to be caused by gas in the stomach and is sometimes relieved temporarily by belching. Like the pain of the so-called "real" angina this lesser pain may be referred to the left shoulder. Sometimes one may detect an obvious lesion of the heart or aorta: more often they show absolutely nothing on physical examination. They are usually more or less neurotic individuals who are concerned, not because of the severity of the pain, but because it is situated in the region of the heart. When asked if they would consult a doctor if they had a pain of equal severity, for instance in their shin, they invariably say, "No."

Nothnagel who studied four hundred and eighty-three cardiac cases found that 60% of the cases of aorta insufficiency and 68% with aortic insufficiency and stenosis complained of this symptom, while 7% of the cases of mitral insufficiency had precordial pain in 17% of mitral insufficiency with stenosis.

Considerable evidence has been accumulated both in this country and in Europe to show that a very large number (80 to 90 per cent.) of cases of aortitis are due to syphilis.

I have records of about fifty patients who complained of more or less constant pain in the region of the heart; for the most part unaccompanied by physical signs.

They will be discussed at another time. It is sufficient to state that in many there is reason to believe that the symptoms were due to a prenatal syphilitic lesion of the aorta or coronary arteries, which belief was strengthened by the marked improvement or complete recovery that usually followed specific treatment. The following case is typical of this group:

CASE 3. A married man of thirty-two consulted me over two years ago because he "choked up" and belched gas. He had always enjoyed the best of health and was an unusually robust appearing individual. His father and mother were living, the latter was stated to suffer slightly from "indigestion."

Some six months before, after eating peanuts, he felt faint and since then every few days he has had an uncomfortable feeling of pressure in the region of his heart. He also has experienced some slight pain in his left shoulder. He has observed that the pain is worse when he lies on his left side but at no time does he suffer intensely, though he appears very nervous because his distress is in the region of the heart.

He smoked excessively, exercised but little, used alcohol moderately and ate heartily of meat twice a day. Eight years ago he had gonorrhea which promptly responded to treatment. Pulse rate was 80, systolic pressure 125, diastolic 110. There was

no enlargement of the heart but along the left border of the sternum the first sound was not entirely clear though it could scarcely be designated as a murmur. His urine, except for excessive amount of indican, was negative. A low proteid diet, exercise, buttermilk with a small dose of bromide after meals was prescribed. Tobacco was also interdicted.

Following this treatment he seemed to be better for the first week. Soon, however, he complained of "little sharp pains" in the precordial region occasionally going to the left arm. Never in the right arm. Sometimes this pain lasted an hour or so and other times it was of much shorter duration. He has several of these attacks every day. Except for this, he assured me he "felt like a two-year-old."

Because the pains increased and as he gave a strong luetin test he was put on injections of sodium cacodylate hypodermically, alternating with mercury salicylate.

After several weeks of treatment the pains completely disappeared but about five months later they recurred slightly. At this time the Wassermann was negative, the luetin was strongly positive.

He was given several injections of mercury and three of neo-salvarsan. Ten days after the last injection he said he could lie on his left side without discomfort and he had had no pain whatsoever through his left chest since the last treatment.

His Wassermann six weeks after treatment was discontinued was again negative, the luetin was slightly positive. He has had no treatment for over a year and within a few weeks he told me he was feeling first rate and had not had any recurrence of the pain. It was assumed because of his apparent good family history and from the fact that he had gonorrhea eight years previously, that he had acquired syphilis then. As it will appear from the study of his mother's case, which follows, it is probable, however, that his trouble was due to hereditary syphilis.

CASE 4. About a year and one half from this time his mother, a woman of fifty-five, consulted me because she was exceedingly nervous and could not sleep at night. She also complained of shortness of breath on exertion and a "beating" in her neck.

Her family history was not remarkable. She had had seven children, five of whom died in infancy and childhood. The son is the case just previously described. Her daughter is subject to severe headaches for which she has unsuccessfully sought relief.

The mother was a large woman whose systolic pressure was 193 and diastolic 143. Except for an occasional extra systole the heart was negative as was the rest of the examination.

The Wassermann reaction was negative, the luetin test was strongly positive. The urine contained neither albumin nor sugar. She was put on potassium iodide and mercury by mouth which was continued for several months. I think she also took inunctions of mercury though I do not find it so recorded. One month later she was sleeping very much better and had ceased to be nervous. Her systolic blood pressure at this time and two weeks later was 150. Nine months later I was told by her son that she was still sleeping well and was not nervous and that her general health was better.

Insomnia, especially in the early morning

hours should not be regarded lightly as it is frequently a forerunner of a serious syphilitic process of the nervous system.

A large and important group comprises individuals with hypertensive cardiovascular disease as syphilis seems to be the underlying factor in a much higher percentage of these cases than we have hitherto supposed.

As the result of a recent study² of a series in which other members of the family were investigated as well as the individual with hypertension, the statement was made that hereditary syphilis plays a very important rôle in hypertensive disease of middle life.

It was furthermore suggested that the families prone to early cardiovascular degenerations are really manifestations of familial cardiovascular syphilis.

CASE 5. A woman of about sixty was referred to me several years ago. For years she had been exceedingly nervous, short of breath, and complained much of precordial distress. Her blood pressure for at least ten years had varied between 180 and 200. Her father had been much addicted to alcohol and died at an early age, of an unknown cause. Her mother had also died early in life but the nature of her illness was unknown. The patient's husband is a man of exemplary habits and has never had any venereal disease. The heart was somewhat enlarged to the left but the sounds were clear at all times and the action was perfectly regular.

This patient complained mostly of a pain under the left breast which was somewhat relieved by compressing that side of the thorax firmly with her hand. For several years her condition did not change and every few months the services of a trained nurse would be required because of nervous attacks.

The Wassermann was negative, which may have been due to the fact that she had been on small doses of potassium iodide for about ten days. However, the Wassermann reaction is very often negative in adults with hypertensive cardiovascular disease due to syphilis when the luetin test is positive. The value of the luetin test is considerably enhanced if the patient be put on mixed treatment for a week before it is used and for about two weeks thereafter. The reaction may be delayed two or three weeks. This test was exceedingly positive, in this case, the pustule resulting being very large. She has received injections of mercury with potassium iodide by mouth for over a year with a marked improvement. She has not required the services of a nurse during the past winter and has gone out more socially than in many years. She has still some distress through the left breast but it is much less frequent and not so severe. She is also inclined to be nervous but this symptom is also markedly diminished.

The dyspnea on exertion has not materially changed. The phthalein kidney function before treatment was instituted was 22% the first hour and 7% the second hour, total of 29%.

Eighteen months later it was 47% the first hour and 23% the second hour, total of 70%.

Recently when she was particularly free from

nervousness her systolic pressure was 150, diastolic 80.

Early in September she stated that it had not been necessary for her to go to bed this year because of hay fever, for which she was particularly pleased, as for many years she has spent from two to four weeks in bed because of that trouble and the weakness resulting therefrom.

I do not think one is warranted in assuming that her treatment was responsible for this, except in so far as the improvement of her general condition is concerned.

Sherrick³ has recently made the statement that 99% of all non-syphilitic individuals will react positively to the luetin test if they have received potassium iodide previously or after the test has been given.

His article, however, is not convincing, as the cases he considered as "non-syphilitic from every standpoint" included patients suffering from brain tumor, hysteria, sciatica, traumatic neurosis, chronic nephritis, epilepsy, exophthalmic goitre and arterial sclerosis, any one of which might be due to hereditary syphilis; a negative Wassermann being of no value in excluding hereditary syphilis in adults. It furthermore would seem that the reaction he obtained following the injection of agar and emulsion of starch, might have been an evidence of "*umstimmung*," or skin irritability which syphilitics often possess to a variety of substances.

I have frequently observed the *umstimmung* at the site of the "control" which Noguchi at first used on the opposite arm, to be particularly marked in cases that had received treatment. Frequently it was as strong as the luetin test itself.

In hypertensive cases with a systolic blood pressure of moderate degree very definite improvement will sometimes follow mercury injections and potassium iodide if continued over a period of several months. When the systolic pressure reaches two hundred or above it is questionable whether improvement will follow.

I have given salvarsan to several of these cases but except for the relief from anginal pains I have been more impressed with the improvement that follows mercury and potassium iodide.

To cope with the problem of syphilis it is essential to look upon it as a familial disease. We are only doing a small part of our duty when we treat the patient with interstitial keratitis. His father and mother, now in middle life, are quite likely beginning to show some of the late manifestations of syphilis and his sister, perhaps about to marry, may have a positive Wassermann.

All members of the family should be examined when a case of syphilis is discovered.

Practically, this is often impossible, as the average citizen who feels well does not want to be tested and refuses "to doctor," even if the tests prove him specific. This fact, however, in no way excuses the physician from doing his duty.

The next three cases illustrate this importance.

CASE 6. A widow in middle life, who had enjoyed good health prior to her marriage, consulted me because of several hemoptyses. The physical examination showed many râles at both apices and over the right lower chest in front. Tuberculosis was diagnosed and she was sent to a sanatorium. There were several points in her history, however, that required further investigation. In the first place she had had headaches and been dizzy for a number of years and her hearing was impaired in the left ear. She had also had darting pains in the ends of her fingers "like needles", and in common with all the members of the family she had suffered from "rheumatism" which, upon inquiry, was shown to be vague pains in different parts of the body. Her husband had died suddenly at the age of fifty-eight. He had been a widower for a few years prior to his marriage to my patient. Through the courtesy of his eldest son by his first wife I ascertained that all of the children of his first marriage were in excellent health save my informant who had traumatic epilepsy. At my request he had a Wassermann made which was negative. My patient had a very strong Wassermann and luetin test. Through the courtesy of Dr. McPartland I was enabled to test her own son and daughter. The latter, about thirty, was undersized, stunted in appearance, of unhealthy color, and very excitable. For years she had suffered from headaches of extreme severity which were often accompanied by vomiting and at times required morphia. The son was illegitimate, being born after her husband's death. He had suffered from some congenital eye disease in early age and at one time a large amount of skin "peeled off" his body. He is quite immature mentally. Though twenty years of age he is quite happy to be about in an "Indian costume" and play and sleep in a tent. He attends to his work, however, every day, though his mother is concerned that he is so interested in childish amusements.

Both son and daughter exhibit strongly positive Wassermann and luetin tests. The latter experienced much relief from her headaches after specific treatment but they recurred later on when treatment was stopped.

The mother's headaches were at times so severe that an examination was made of her spinal fluid but it was entirely negative. She was greatly improved by neosalvarsan and mercury. Her hair and eye brows were quite grey when the treatment was instituted; subsequently many new hairs appeared all of which were black, which was the original color of her hair.

It seems probable that her husband contracted syphilis sometime between the death of his first wife and his second marriage.

The family history in this case was particularly interesting because all of the members had suffered for years from what they considered "rheumatism", that is vague pains in different parts of the body, sometimes in the "muscles" again in the "bones", then in the joints. These pains are more apt to be worse in bad weather. The "rheumatism" of this family was completely dispelled by specific treatment. We are only just beginning to learn that hereditary

syphilis of the bones, periosteum, synovial membranes is a common condition. Very often it is considered tuberculous.

CASE 7. A young man of twenty-five referred to me by Dr. Swett first noticed a stiffness in the calf of his leg some five or six years ago, when playing baseball. This was not constant and caused him no pain. He has, however, limped for about two years and when sitting quietly he has a "nervous feeling" in his leg. Shortly after the onset he noticed that his

FIG. 1.

Case 7. Hereditary syphilis of knee simulating tuberculosis.

knee was swollen. (Fig. 1). He had taken "rheumatism medicine" and for the past year had been having it massaged. The x-ray picture was not conclusive though suggestive of an early tuberculous focus in the inner condyle of the femur, which seemed probable, as the Wassermann reaction was negative. He entered the hospital for further study and possibly for the resection of the joint. He was given the tuberculin test and a general reaction resulted but no focal reaction occurred in the knee. He was then given the luetic test which was positive.

Upon examination the only stigma suggesting congenital syphilis was a very high narrow palatal arch. I found, however, that his mother had a systolic blood pressure of over 200. It was furthermore learned that his father had had a venereal disease prior to his marriage and had been sexually immoral. His mother had two miscarriages and her oldest daughter became deaf when about thirteen and has "awful headaches with noises in her ears." Glasses relieved her somewhat. This sister, whose palatal arch is also narrow and high, has a very positive Wassermann reaction. The mother's Wassermann is negative but the luetic was positive.

Perhaps, the most instructive thing about this case was the fact that his Wassermann, cholesterin antigen, was negative. Everyone who writes about the Wassermann states that a negative test does not exclude syphilis, but nevertheless, the majority of physicians discard the diagnosis of syphilis when one or two negative reports are obtained. Yet the failure to find tubercle bacilli in the sputum by no means excludes the possibility of tuberculosis when the symptoms and signs point to that disease.

It is undeniably true that innocent persons free from lues have had the stigma of syphilis attached to them, due to laboratory mistakes, but the number of persons equally guiltless, though suffering from syphilis, who have been denied active specific treatment because of a negative Wassermann, I believe, is greater.

This case further demonstrates the value of the subcutaneous tuberculin test in bone and joint lesions. Though he had a general reaction showing that he had a tuberculous focus, there was no reaction in the lesion in question. His response to salvarsan and mercury has been very gratifying.

CASE 8. An unmarried girl of twenty-one referred to me by her physician. Following an injury about a year previously she noticed a swelling in the back of her left leg. As there was much that suggested an inflammatory process an operation had been performed and a mass removed, which proved to be a gumma. A Wassermann reaction was subsequently very positive.

A careful study of this young woman and her family, however, would have suggested the possibility of congenital syphilis and this operation would have been avoided.

In the first place, although she was twenty-one years of age, she did not appear, either physically or mentally, to be over sixteen.

Her palatal arch was high and narrow and she stammered badly. I do not know what the relationship between congenital syphilis and stammering is but several patients who were badly affected with this distressing condition all had some manifestation of hereditary syphilis. It seems that it might be classed with the dystrophies due to this condition. It was, furthermore, necessary only to see the mother to have syphilis suggested, because of the ptosis of her left eye lid. When questioned as to the health of the other members of the family the information was obtained that the next youngest daughter had been told that she had a serious "blood disease" some years before when she consulted a throat specialist because of a perforation of her palate. The mother and younger sister who is "all right" now had strongly positive Wassermann's.

Again we see the great importance of looking upon syphilis as a familial disease. Had this been done when the sister consulted the throat specialist and had he insisted upon the other members of the family being examined, it is quite probable that adequate treatment would have prevented the development of the gumma in the leg of this patient as well as the periostitis which

the mother developed later on. This case is also of interest because of the apparent effect of trauma in the development of the syphilitic focus.

The detection of the stigmata of hereditary lues in the children may explain an indefinite illness in a parent as the next case illustrates:

CASE 9. A woman of sixty-two complained of stomach and intestinal trouble of four years' duration. Questioning, however, brought out the fact that there were no symptoms definitely referable to the stomach but she had suffered from diarrhea for several years, and each day she would have four or five liquid stools. The odor was described by the patient as being rancid. Much of the time she had what she described as a "slow pain" in the upper part of the abdomen. She has also suffered from "bilious attacks" for several years.

Several years ago she was very ill and the diagnosis of pyelitis was made, and for many months she took urotropine off and on with benefit. She suffered considerably from headaches in the morning and has lost a great deal of strength lately. For this reason she has been forced to lead a very much less active life than formerly.

There was nothing particularly note-worthy in her family history. She looked to be much older than she was and the only thing discovered on physical examination was that the liver was considerably enlarged and moderately tender over the left lobe. The rectal examination was negative.

With a person of her age one's first thought would be a malignant condition involving the liver and probably the large intestine as well. The "bilious attacks," however, were very suggestive of gall stones.

Her two daughters accompanied her to the office, and it was about this time that the older daughter smiled. It could be truthfully said that she had an "illuminating smile" (Fig. 2) as the anterior sur-

filled with gold. This daughter, who was thirty-one years of age, also had a very heavily furrowed tongue, and when eight years of age, she had also had an acute glossitis and the tongue was nearly perforated. As a child she had suffered much from growing pains in her legs and has always suffered from severe headaches. She says she is "always tired." The other daughter had a high, narrow palate. Upon questioning the mother, I ascertained that her husband had died from "general debility" at the age of fifty, and that he had been very immoral sexually.

Three of her pregnancies were stillbirths. The mother and older daughter had a negative Wassermann, but in both the luetin test was positive. The mother's strength and endurance were greatly increased by inunctions and potassium iodide, but as she continues to have an occasional bilious attack, especially at night, an operation has been advised on the assumption that she may also have gall stones. Syphilis of the liver, however, may simulate gall stones very closely.

I cannot take up the question of the teeth in the diagnosis of hereditary syphilis but I feel strongly that syphilis leaves its mark on the teeth much more frequently than we are apt to think, and that most of the dental hypoplasias are the result of hereditary syphilis.

The next three cases illustrate different types of "rheumatism".

CAES 10. A young unmarried woman of twenty-three had suffered from "rheumatism" for several months before I saw her in March of this year. She was an exceedingly healthy child, free from headaches and growing pains. About seven months previously she first noticed pains across the base of the toes of the left foot. This pain continued both day and night.

Under the belief that it was due to a fallen transverse arch, a support was made which, however, seemed to increase the pain. Thinking that it might be an infectious arthritis, her tonsils, which were unhealthy, were removed in the fall of 1914.

No improvement followed, however, and the pain shortly thereafter extended to the right knee, then to the left foot. The pain was severe, constant and did not respond to any treatment, although various schools of therapy were tried. Later on, the left knee became involved; finally the heel of the right foot, and for five weeks the patient was confined to bed because of the pain caused by walking.

There has been no improvement since the patient took to bed. She was a large well-nourished young woman, slightly pale, with excellent teeth and gums, and a normal palatal arch. Her pupils reacted to light but were not absolutely regular. The knees were swollen and pressure over the patellae, the inner and outer condyles of the femorae and upper part of the tibiae was painful. The right foot at the base of the great toe was swollen and tender and also the lower part of the os calcis. Passive motion of the knees, however, was not painful.

This was the most significant thing in the whole examination. The tenderness was greatest over the epiphyseal line. In other words she did not have an arthritis of her knees, but rather an epiphysitis of tibiae and femora. Her Wassermann was strongly positive. Her father had a syphilitic infection four years after his marriage, and has had several strokes

FIG. 2.

CASE 9. Small hyperplastic areas in many of the teeth, commonly attributed to diseases of childhood, but in reality usually due to hereditary syphilis.

face of all the incisors were studded with a number of small hypoplastic areas, many of which had been

of apoplexy and exhibits a positive luetin test though a negative Wassermann.

The next case I recall with embarrassment.

CASE 11. A man of forty-two was referred to me by Dr. Wm. Bartlett for an opinion as to the condition of his lungs. He spoke no English and through an interpreter, whose English was very limited, it was learned that he had been in good health until five years ago but that since then he had been weak and had a slight cough and at one time the sputum had been very slightly blood-streaked. Nocturia three times. A brother had died of tuberculosis a few years before, but the patient had not been with him. He had fine râles, on coughing, over the lower anterior aspect of both lungs and a few at the right apex behind. The heart did appear to be enlarged but the sounds were very faint, being barely audible at the base.

There was no albumin in the urine. The diagnosis made was "tuberculosis not likely; myocarditis with secondary changes in lung"; digitalis was advised.

A year later I discovered the patient in the Hartford Hospital and at that time he presented definite signs of aortic and mitral insufficiency. My embarrassment may be imagined when the house physician pulled down the bed clothes and drew my attention to a number of large scars along both tibiae! I had not looked at his shins.

CASE 12. A colored man of fifty-five consulted me in September, 1914, because of stomach trouble which had persisted for about two years. He had never experienced severe pains but was flatulent and somewhat "sore". This had increased in the last few months. He sleeps well and has a good appetite but has lost considerably in weight. His family history was good. The radial arteries were slightly thickened. Heart and lungs were negative. Except for a movable right kidney the abdominal examination revealed nothing. We have here then a man complaining of digestive disturbances, accompanied by considerable loss of weight and, as he is fifty-five years of age, malignant growth is the first thing one thinks of. Further questioning, however, elicits the fact that sometime ago he had some rather severe pains in his legs, and that the sensation over the upper part of the left foot was poor; "it felt numb." He furthermore has had slight incontinency of urine for several months. He also complains of some pains in the lower part of his back which were "crawling in nature." On examining him further it was noted that both pupils were irregular and almost immobile.

He moreover had no knee jerks. His blood, Wassermann, was strongly positive, but negative in the spinal fluid until after he had had considerable treatment, when it became strongly positive.

This early tabetic, masquerading as a simple case of indigestion, has been very much improved since intramuscular, intravenous and intraspinal treatment has been instituted. Not only have his digestive disturbances disappeared, but his general health is also markedly better. He still has the numbness in his foot, but very rarely any pains in his legs.

CASE 13. A woman of thirty-two was referred to me by Dr. Travis of New Britain, for an examination of her lungs, as she had a slight cough and was weak. I did not find any evidence of pulmonary or

cardiac disease. She had always been a "weakling" she stated. As a child she fainted easily and was never strong. She had much headache, which was relieved by glasses. She is sure she has indigestion as she has a feeling of pressure below the sternum. This does not bear any relationship to meals, however, and is apt to be more marked on awakening in the morning and is accompanied by a disagreeable sensation, hardly a pain, which extends upward on the left in the precordial region and sometimes through to the left shoulder.

For some time she has occasionally felt a numbness in the fingers of her left hand, chiefly the little finger. Being out in the cold often brings it on. At such times her finger at first becomes very white, then marked congestion follows, at which time it "throbs". She has frequently noticed it on retiring after eating too heartily. She has slept very poorly for a long time, especially in the early morning hours. She is a frail woman, weighing 104 pounds, with normal pupils but no knee jerks. She stated that her physician had told her several years before that the reflexes were not normal. There was no Achilles reflex and no Babinski.

She had moderate enteroptosis. Her father died at sixty-three of "heart trouble". He had not been a strong man and had suffered from lead poisoning. Her mother informed me that he had contracted syphilis at the time of the Civil War and that he had infected her prior to the birth of their first child. The mother's first three pregnancies were premature, living only a few days, and all were "bleeders". The fourth died at the end of the first week. The fifth was a still birth at the seventh month. The sixth is now living with a spondylitis and the next is the woman herein described. She gave a very positive hemorrhagic luetin reaction but the Wassermann on blood serum and spinal fluid was negative. There was no globulin in the latter and there were six cells per cm.

Though Fournier years ago drew attention to this weakling group, it has received but little attention since. They are always "ailing" yet with nothing definite the matter. They are prone to all types of infection especially to tuberculosis, and they often died. Fournier tells us, of "nothing at all so to speak." The women of this group are quite apt to be sterile.

The case cited is also of interest because she presented the picture of Reynand's Disease. I have seen one other case in an adult woman who had a prenatal syphilitic infection. Bosamvi⁴ has reported two cases due to hereditary syphilis, both of whom were cured by specific treatment. I have treated a number of this "weakling" group with very small doses of salvarsan and mercury both in the form of inunctions and injections but the results for the most part have been very discouraging. But is it not quite likely that some of these unfortunate individuals might now be enjoying their rightful heritage of good health if they had received thorough treatment in their early childhood?

CONCLUSION.

The late symptoms of lues are often vague but their indefiniteness should put us on our

guard. "Chronic rheumatism" and "chronic headache" mean "chronic syphilis" in many cases. The physician who does not avail himself of all the newer tests before making these diagnoses assumes a grave responsibility. By carefully studying other members of the family some evidence of syphilis may be detected when nothing can be discovered in the patient himself. Of supreme importance is the realization that syphilis is a familial disease. It is a problem for the family doctor, not for the genito-urinary specialist or the dermatologist. Finally, we must not lose all sense of perspective and become blind worshippers at the shrine of Wassermann. Admitting that it is the most valuable laboratory test yet discovered, it is not infallible. Positive in nearly all early cases of syphilis it is often negative in the late cases, especially in adults with a prenatal infection. Even when positive it does not prove absolutely that the lesion in question is due to syphilis. The Wassermann and luetin tests should supplement, not supplant, the complete history and careful examination.

SOME OF THE ANATOMIC-PATHOLOGIC PROBLEMS IN TUBERCULOSIS.*

BY FRANCIS M. POTTENGER, A.M., M.D., LL.D.,
MONROVIA, CAL.,

Medical Director of the Pottenger Sanatorium for Diseases of the Lungs and Throat, Monrovia, Cal., and Professor of Diseases of the Chest, College of Physicians and Surgeons, University of Southern California, Los Angeles, Cal.

Bovine and Human Infection versus Bovine and Human Clinical Tuberculosis. In this short paper I desire to call attention to several very important problems in the realm of anatomy and pathology, which are as yet unsolved, although they have apparently been discussed from nearly every conceivable standpoint.

The question of bovine and human infection has received more consideration during the last few years than almost any other subject connected with tuberculosis, and yet the relationship is far from settled. The scientific world now recognizes it as a fact that bovine tuberculosis infects human beings; but believes equally that the human bacillus is the most common source of infection in human tuberculosis. While the non-pulmonary forms of the disease, those which are particularly prone to infect children, are often considered to be produced by the bovine bacillus, pulmonary tuberculosis,

which most commonly affects adults, is considered to be nearly always due to the human bacillus. This has been accepted as meaning that tuberculosis in childhood is conveyed to the human race through milk and meat, while tuberculosis in the adult is probably conveyed from one infected individual to another; but such reasoning will not hold, for we know that the human being, both in childhood and adult life, is exposed to human and bovine bacilli, and that both gain entrance to the body.

As far as we know, no matter how bacilli are taken into the system, and no matter what kind of bacilli, if in sufficient numbers, they produce an infection. They may be primarily implanted in other tissues of the body, such as seems to be the case from Ghon's reports; but this is only temporary and, sooner or later, they find their way into the lymph glands and produce lymphatic tuberculosis.

So far as we know both bovine and human bacilli take the same course. Pathologists who have recovered the bacilli and studied them carefully show that in early life infection is often of the bovine type, while in later life it is almost always of the human type. In this connection I would like to mention that infection in childhood may take place in any part of the body where bacilli are detained in their course; and is as likely, or more likely, to be extra-pulmonary than pulmonary. The reason for this I shall discuss farther on in this paper. It is necessary to cite at this point the very important fact which seems to be well established by pathologists today, namely that the primary infection in the child gives a certain amount of immunity to the disease and makes further infection much more difficult after a primary infection has once been set up in the body; and the further belief that the later infection of the lung or other portion of the body, which manifests itself in adults is, in a very large per cent. of cases, a metastasis from the primary infection which took place during childhood. If, then, both human and bovine bacilli are taken into the body during early life; and, if they both produce a specific immunity against themselves; and, if they both become implanted in the tissues and then follow the same course, either going on to active disease, healing or remaining quiescent for a time, to become active later and spread to other parts of the body; and, if the bacillus recovered from the focus in the child is often of the bovine type, while the bacillus recovered from the infection in the adult is almost never of the bovine type; does it not seem that one of two things occurs: either that bovine bacilli find the soil so unsuitable to their growth that unless they produce active disease at once they die out; or, that the bovine bacilli, remaining in the human tissues during a period of years, finally adapt themselves to the human tissues, and in the process change their morphological and reactive peculiarities and assume the human type? Such

* Read before the thirty-second annual meeting of the American Climatological and Clinical Association, San Francisco, Cal., June 18 and 19, 1915.

transmutation is far from unlikely. We must look upon the human and bovine bacilli as being different types of the same organism, and varying only because of their different habitat; the one adapting itself to the bovine tissues, and the other to the human tissues. Why could it not be that by subjecting one to the tissues of the other's host over a prolonged period of time that it would take upon itself the characteristics of the bacillus which naturally inhabits that soil?

Primary Focus and Primary Metastasis. There has been a great deal of discussion on the question of the primary foci in tuberculosis; and also on the primary metastasis from this focus. In tuberculosis of the lungs pathologists have been divided in their opinion as to whether or not the tuberculosis of the peribronchial glands is secondary to the pulmonary involvement or whether the pulmonary involvement is secondary to a primary infection of the glands. This discussion goes on without any particular advantage to the adherents of either theory. Most observers, however, believe that the glandular involvement is first, and that the pulmonary involvement, that is, the chronic apical involvement which particularly characterizes tuberculosis of the adult, is a metastasis from this.

Ghon has recently, however, revived interest in this important discussion and brought forth proof, which seems almost incontrovertible, that the primary focus in tuberculosis is often found in the lung, the infection in the peribronchial glands being secondary to this. To this discussion I would like to add the following observation, which seems to make it possible to harmonize these differences. There is a marked difference in the behavior of the infection which takes place in an animal or human being who is healthy at the time of inoculation and one who is already infected. An infection, when once present, produces a hypersensibility of the cells, and in this way creates a defense against further infection by the same micro-organism.

The mucous membranes and other tissue of the non-infected organism show no specific defense, consequently offer little opposition to the passage of bacilli. This we see in the readiness with which bacilli pass through the tonsils of the little child and affect the cervical glands; or the bronchi and affect the peribronchial glands; or the intestine and affect the mesenteric glands, without being stopped in the intervening tissue. The first important barrier met, prior to the time infection occurs, is the lymphatic glands, the particular structures which are peculiarly active in the defense of the organism at this period of life. After an infection has occurred, however, and the cells of the body have become sensitized to the bacillus and its products, cellular defense becomes general. Then there is a specific opposition offered to bacilli at every point of entry, the degrees varying probably with many circumstances. This was beautifully demonstrated years ago by Koch's experiments, showing that the healthy guinea-pig, when inoculated, shows a

slight temporary inflammation at the point of inoculation, which disappears after a short time, but that a very marked involvement of the neighboring lymph glands takes place; while the inoculation of a guinea-pig which is already tuberculous behaves in a very different manner. This difference depends upon the hypersensitive condition of the body cells. The protective influence of the previous infection shows itself in an attempt on the part of the body cells to limit the infection to the point of inoculation; consequently a nodule appears, followed by inflammation, and after a few days, ulceration. The infection, being localized, is thrown off, the neighboring lymph glands remaining free from involvement. Such, my study leads me to believe, is the case in the natural infection in the human body. If tubercle bacilli pass through the mucous membrane of the tonsils or any portion of the upper air passages or lungs or lower air passages, or intestinal tract, they are apt to pass at once to the lymph glands; but in instances where they fail of this and become implanted locally in the tissues, they form small nodules such as those described by Ghon in his remarkable work. But these foci are extremely small, many of them not being larger than peas, or small beans, or marbles. The peribronchial glands draining these areas, on the other hand, are quite large and bear the brunt of the infection. Through this infection the hypersensibility of the body cells is produced, and then when bacilli are carried from these glands to other parts of the body, whether it be the lung, joint or bone, there is at once a tendency to limit the infection. These metastases usually occur through the blood, and are produced, as a rule, by few bacilli. Escaping into the blood, the bacilli are diluted and for the most part destroyed. Those which are strained out in the small capillaries to produce a local infection, are probably reduced in virulence; and when they come in contact with the action of the sensitized cells their virulence is further limited so that the lesion which results is either abortive in character or a non-virulent one. This primary metastasis, as a rule, is quiescent for some time before it produces active symptoms; but from it, eventually, other metastases occur. Even though it may be larger than the primary focus in the lung, described by Ghon, it is not followed by marked enlargement of the regional lymph glands. We notice the same freedom from infection of the lymph glands in secondary metastases in the larynx and intestinal tract. Applying this principle of local hypersensitiveness and its effect on attempted inoculation to our study of infection, it offers a key to the determination of the primary focus and the secondary metastasis.

Why the Apex of the Lung is Involved in the Adult, While Any Portion May Be Involved in the Child. In discussing this question the very fact that infections in childhood are more apt to be non-pulmonary than pulmonary, while infections in adult life are more commonly pulmon-

ary, and not only pulmonary, but begin at the apex of the lung, leads to the natural inquiry as to what difference exists in the conditions which surround infection in child life and those which surround it in adult life. The involvements of the lung, bone, joint, meninges, or other structures than the glands, must be looked upon for the most part as metastases, which take place through the blood, although it is possible that bacilli might be taken in through the mucous membranes, particularly those of the tracheal tract, and be carried through the thoracic duct and poured directly into the blood stream, to be strained out in any of these parts, without a primary focus occurring in the lymphatic glands. Such bacilli would go through the lung first, and in case they should escape lodgment in the pulmonary capillaries, might go on and produce infection in some portion of the systemic circulation; but statistics show that bacilli in the child are less prone to find lodgment in the capillaries of the lung than they are in other portions of the body. The fact that predisposition to pulmonary involvement does not exist in the child, therefore, leads us to the inquiry, is there any anatomic or physiologic difference between the lung in child life and adult life which would make it, particularly the apex, more prone to involvement than any other portion of the body? In answer to this question there are very important changes which take place and which seem to be fully capable of making this difference in localization. These are the changes which come about in the shape of the thorax and the growth of the lung as the child increases in years.

At birth the jugulum is on the level with the last cervical vertebra, but after the child has assumed an erect position for a time, the anterior wall of the chest drops. This proceeds rapidly, so that by the time the child is six or eight years of age the anterior portion of the first rib is on a level with the third dorsal vertebra. In this sinking of the anterior portion of the chest the apices of the lungs are crowded together at a time when the lungs as a whole are increasing in size. Consequently the respiratory motion is relatively lessened, and this favors retardation of the blood and lymph flow in the apices of the lungs, and in this way favors the implantation of tubercle bacilli at this point. This disposition is particularly exaggerated at puberty when the lung takes on an enormous increase in growth, doubling in size within the space of one or two years. The upper portion of the chest being flattened, this increase in growth is reflected in a relatively greater apical compression. As arguments in favor of this being a factor, I would like to call attention to the further fact that the primary metastases rarely occur in the base of the lung, where the motion is not retarded; and I would further call attention to the fact that the same localization of carbon takes place in the lungs as of bacilli. While in the child the pulmonary tissue is

comparatively free, the peri-bronchial glands and sub-plenural spaces being filled, in the adult the pulmonary tissue itself, particularly in the apices, is studded with carbon, while the pulmonary tissue in the lower lobes is comparatively free.

A Physiological Suggestion for the Cause of the Small Heart. The small heart in tuberculosis has been the subject of a great deal of discussion from the time tuberculosis first assumed clinical importance. Benecke, Rokatsansky, and others observed post mortem that the heart was often small in tuberculates, smaller than in other individuals. Brehmer, being convinced by their observations, decided that tuberculosis was due to the inability of the small heart to nourish properly the lung, and consequently founded a therapy on the principle of improving the functional capacity of the heart. When he established his sanatorium at Goebersdorf he built it at the bottom of a hill, and laid the grounds out in paths representing certain definite grades; and each patient, according to the functional capacity of his heart, was assigned a certain amount of hill climbing to do. This was guarded most carefully by Brehmer, and a systematic therapy based upon exercise, was established.

The fact that the heart in tuberculosis is small has been substantiated later by clinicians and particularly by the orthodiagraph. The important fact has been brought out that not only is the heart small in late tuberculosis, where it might be due to general malnutrition and degeneration of tissues, but also in early tuberculosis, where the tissues have not yet suffered degeneration. In this connection, the small heart is found in persons of normal build as well as those of enteroptotic build. Further observation brings out the important fact that there are other conditions in which the small heart is found. It is found in the individual of the enteroptotic build. If we compare the enteroptotic individual and the tuberculous, particularly one suffering from early tuberculosis, we find one condition in common which produces changes in the cardio-vascular system. A striking feature is common in the deficiency in the inspiratory act. In both of these types of individuals we have a deficiency in the action of the diaphragm. In the tuberculous, not only the diaphragm, but other muscles of respiration are limited in action. Wennekebach¹ has described this very fully on the part of the patient suffering from enteroptosis. The writer² has called attention in numerous papers to the effect of a deficient inspiratory act upon the tuberculous individual.

The maintaining of the normal circulation of the blood depends primarily on the action of the heart itself and the condition of the blood vessels, but secondarily, the circulation is greatly facilitated by the inspiratory act. The inspiratory act opens up the chest cavity, increases the negative pressure in the large veins and heart chambers, and in this way sucks the blood into the right heart. This action at the same time re-

lives the systemic veins. When there is any deficiency in the inspiratory act, as we find consequent upon a deficient action of the diaphragm in enteroptosis and because of the reflex disturbance on the part of the diaphragm, as well as other respiratory muscles in tuberculosis, we have a lessening of the suction action on the circulation and a reduction in the amount of blood delivered to the heart, consequently a reduced amount of blood in the heart and a reduction in the output of the ventricle. The condition which produces this change being constant in tuberculosis, the heart is obliged to accommodate itself to a lessened content and a lessened output, and as a result of this it becomes smaller in size.³

ACUTE OTITIS MEDIA IN INFANCY AND EARLY CHILDHOOD: AVOIDABLE MISTAKES IN DIAGNOSIS, PREVENTION, TREATMENT.*

By WM. R. P. EMERSON, M.D., BOSTON,

Professor Pediatrics, Tufts College Medical School.

ACUTE otitis media is, I believe, the most frequently overlooked affection of infancy and childhood. Not only is it not correctly diagnosed by the profession as a whole, but it is also sometimes overlooked by the pediatrician, and in infancy its significance is often underrated by the aurist himself. The prevalence of this disease is due to the relative increase in frequency of nasopharyngeal affections in early childhood, and the readiness with which the necessary sinuses are blocked, which, in the case of the Eustachian tube, leads to the formation of a closed cavity in the middle ear with consequent infection and abscess formation. It is difficult to realize that earache is not localized in infancy. In childhood also, where otitis media occurs as a complication, this symptom is obscured by the general toxemia. The symptoms of acute otitis media may be those of pneumonia, of meningitis, abdominal or simply an intensification of symptoms due to the disease which the otitis complicates. As this disease so frequently leads to involvement of the mastoid cells, to edema of the brain, or to the entrance of bacteria into the general circulation, failure to make an early diagnosis may be fatal. An appreciation of the significance of this affection should lead to the taking of proper steps to remove causes that may seriously affect the hear-

ing, the development and the future health of the child. The following cases illustrate the more common sources of errors in diagnosis.

CASE 1. Alice D., age two years, previously well, began to be feverish and vomited on the morning of December 13. She put her hand to her right side saying "hurt". Her bowels had not moved for two days. She had a history of digestive upset the previous summer and Thanksgiving. At five o'clock in the afternoon her temperature had increased to 104 and she had a convulsion. Her attending physician made a diagnosis of an inflammatory process in the abdomen and considered an exploratory operation.

She was seen in consultation at 6 p.m. Her physical examination was negative except for signs of adenoid tissue in her throat, and the presence of marked abdominal tenderness. An examination of the right ear showed slight congestion along the handle of the malleus. The ear was opened by Dr. Frederick Jack. The patient almost immediately fell asleep. Next morning the temperature was 100. At two o'clock it was 102.6 and at six o'clock 105 and the patient had another convulsion. An examination of the other ear showed a condition of the drum similar to that of the first. The second ear was opened by Dr. F. P. Emerson. The next morning the temperature was normal and remained so. There were no further symptoms except for a slight discharge which continued for 48 hours.

CASE 2. Stephen G., age three years, was brought into the out-patient department of the Boston Dispensary. His temperature was 104, his mental condition clouded. He had general tenderness of the muscles, retraction of the head. Kernig's sign was present. In the chest there were signs of bronchitis. A diagnosis of early meningitis was made in spite of the withdrawal of 20 c.c. of clear fluid by lumbar puncture and a normal cell count. A consultation in the out-patient department was held and a second diagnosis of broncho-pneumonia with cerebral symptoms made. He was admitted to the writer's service in the hospital where the ears were examined for the first time. Both drums showed very slight congestion along the handle of the mallei. A double paracentesis was done by Dr. Edward R. Newton, and a drop or two of pus was found in each ear. Next morning the temperature was 100. The cerebral symptoms had disappeared. The temperature gradually returned to normal, the bronchitis cleared up in eight days, and the patient was discharged with a diagnosis of acute bronchitis complicated by a double otitis media.

CASE 3. Edward H., age two years, eight months, had been sick ten days with measles. On Thursday he was doing well. On Friday he began to manifest signs of abdominal pain, which seemed to be paroxysmal. Hot fomentations were applied to the abdomen for most of the night with no relief. The next day the ear drums showed very slight congestion in the upper quadrant, so slight as to make a diagnosis of an inflammatory process uncertain. On the fourth day his condition grew worse, accordingly a free incision was made in each drum by Dr. F. P. Emerson and a drop of pus seen in each ear. Eight hours later the child showed some improvement. The paroxysmal pain disappeared and in 24 hours the patient was comfortable. During this time the temperature varied from 101 to 102.5 and showed no

* Read before the meeting of the New England Pediatric Society, April 30, 1915.

rise with the exacerbation of symptoms. The ears discharged moderately for two weeks when the patient had apparently recovered from the otitis.

However, the prostration was so great that the child was not able to speak for five weeks. On recovery from his sickness it was found that his speech and mental development were put back practically a year. It seems reasonable to believe that the dangerous character of this illness was due to the otitis rather than to the measles.

CASES 4 AND 5. Catherine D., age three years, nine months, had had a cold for a week with slight cough. She became feverish and restless. Her temperature was found to be 102.2. Her physician made a diagnosis of slight bronchitis. The mother asked the physician to examine the ears, which he did not do, but tested them with a watch, pronouncing them all right. The next day the ear drum ruptured and was followed by a profuse purulent discharge which continued for eight days, the patient's temperature ranging from 99 to 101. On the eighth day the other ear was examined only as a matter of routine but found bulging. It was opened under ether by Dr. Harold Walker and at the same time a wider opening was made in the first ear. The temperature the next morning was normal and remained so aside from rising one degree each afternoon. Both ears discharged profusely for about two weeks.

During this time a sister, Beatrice, aged twenty months, was convalescing from broncho-pneumonia. After two weeks of normal temperature she suddenly showed restlessness, the temperature rose to 103.5. The left ear drum showed very slight congestion in the upper quadrant. Measures were adopted to open the Eustachian tube without success. Four hours later the temperature had risen to 104.2 respiration 52. The ear drum was opened by a curved incision, a slight bloody discharge followed. No pus seen. The next morning the temperature was 99, all symptoms disappeared. There was a slight serous discharge for two days and no further symptoms.

Although these cases are selected simply to represent the most common types of aural complication, the following points are of interest: In none of the five cases were there symptoms of earache. In two cases the symptoms were all abdominal, in one meningeal, and in two general, associated with fever. In all of these cases the diagnosis of acute otitis media was made by routine examination of the ear drums, not by localized pain or tenderness. In three cases where the drums were opened promptly with the onset of the symptoms, without waiting for bulging or pus, the symptoms subsided in 24 hours, the discharge in 48 hours, and the duration of the affection was only three days. When there was delay in opening the drum because of failure to correctly diagnose the otitis, a profuse purulent discharge continued for more than two weeks, prostration was extreme, and the ear drums showed considerable resulting injury. Four of the five cases had a double otitis.

From such histories as these it seems fair to conclude that if the attending physician does not examine the ear, in the great majority of cases the diagnosis of otitis media will not be made.

This conclusion is further substantiated by statistics given in 1912 by Dr. C. R. C. Borden based upon the careful study of the clinical records of over 2000 cases of scarlet fever, measles and diphtheria at the Boston City Hospital, and upon the pathological records of 252 autopsies performed by Drs. Councilman, Mallory and Pearce.

	Per Cent.
Clinical diagnosis of otitis media in scarlet fever	11
Pathological " " " " " "	94
Clinical " " " " " measles	28
Pathological " " " " " "	100
Clinical " " " " " diphtheria	2.9
Pathological " " " " " "	82

In other words in over 2000 cases of these diseases otitis media was clinically diagnosed in less than 15%, but in 252 fatal cases otitis media was found present in 92%. There was also found in the 252 autopsy cases, 59 cases of mastoiditis, of which only 6 or 8 were recognized during life, and with but one exception one side was operated on when both were affected. Eighty per cent. of these cases of mastoiditis showed edema of the brain, but the reports also showed that a large number of the affected middle ears had edema of the brain even when there was no mastoiditis. This report reveals an extraordinary situation that has not received sufficient attention. The difference between the clinical and pathological diagnosis is to be explained, I believe, by one reason, namely that the ears were not frequently examined.

This report shows clearly that an examination of the ear drums on admission to the hospital or at the physician's first visit, and additional examinations made only when there are symptoms of otitis, is not sufficient.

In infectious diseases and in all diseases of the respiratory tract the ears should be examined at every visit of the physician to his patient, with as much reason as he would examine the heart in rheumatism or the abdomen in typhoid fever.

Why is this not done?

Perhaps the most important reasons are the discomfort caused the patient by the use of the head mirror and speculum, the special training required for their use, and the difficulty in seeing the drum in infancy and early childhood.

There are now on the market electric ear instruments that have a light inside the speculum that illuminates the whole drum so that it is possible for even an untrained person to get a clear picture without disturbing or alarming the child. With the patient in bed both ears can be examined from the same side with only a quarter turn of the patient's head. One opening in the speculum has a small magnifying glass that is of service in seeing the drum, and in case of paracentesis the point of the knife may be placed through a second opening and inserted into the drum under direct observation and the incision

directed as necessary. The light is so near the drum that small particles of cerumen or even a discharge in the canal do not seriously interfere with vision. With these instruments both ears can be quickly inspected without disturbing a sick patient, and abnormal conditions can be detected that are easily overlooked with a poor light or even with a good light but one that differs from that to which the examiner is accustomed. These advantages, immaterial in examining the ear drums of older children, may be vital in the case of infants whose canal is so small as to make a thorough examination with head mirror and speculum difficult, and frequently impossible.

PREVENTION.

In all primary infections of the respiratory tract and especially in affections of the respiratory tract secondary to contagious diseases care should be exercised to keep the nasopharynx free from mucous and crusts that may cause occlusion of the Eustachian tube. Two or three drops of liquid alboline or of a 10% solution of argyrol may be introduced into each nostril three times a day. During the stage of acute nasal congestion steam inhalations are helpful. An even temperature should be maintained in the room. The child should be protected from strong winds and dust. The air in overheated houses and flats becomes exceedingly dry and consequently irritating. Receptacles for water attached to the side or placed on top of radiators will evaporate one to two gallons daily, appreciably increasing the humidity. In older children the use of the following ointment:

R	
Menthol	gr. vii
Eucalyptol	grs. vii
Lanolin	5 vii
Vaseline	5 ii

applied inside the nostril protects the congested turbinates and so keeps the nares clear. Also in older children in case of excessive discharge from the throat, irrigations of hot normal salt solution two or three times a day frees the nasopharynx from muco-pus. The irrigation may be done by the physician with a metal syringe or by the nurse with a fountain syringe, inserting the glass part of a curved eye dropper into the end of the rubber tube and so directing the stream into the throat and allowing it to flow out into a pus basin with the patient lying in bed. A spray of menthol, 5 grains, and benzoin, 1 ounce, should be used with an atomizer to protect the inflamed mucous membrane from irritation. Swabbing the throat with iodine, 20 minims, to the ounce of glycerine, is also useful. When such measures are taken there is less cough and, therefore, less danger of forcing bacteria into the Eustachian tube.

TREATMENT.

If, notwithstanding these precautions, the Eustachian tube becomes occluded and the drum membrane begins to show congestion along the handle of the malleus, the following treatment should be given to open the tube: a mixture of four drops of adrenalin solution, 1 to 5000, and cocain one-half of 1%, should be allowed to flow through the nostril on the affected side, back into the throat, the patient's head being tipped backward in such position as to cause the solution to flow towards the orifice of the tube. This should be followed in five minutes with a few drops of a 20% argyrol solution, which by its higher specific gravity keeps the tube open. This should be repeated in three hours if there is pain. Frequently the symptoms, congestion and temperature, will disappear with this treatment. If, however, the inflammatory process continues to progress and the symptoms increase, the drum should be incised without waiting for bulging or pus. The operation should be performed by the aurist, if available, otherwise by the attending physician, because the majority of these cases have a mixed infection and a delay of even a few hours may result in rupture of the drum and burrowing of pus into adjacent structures. The attending physician can safely make a curved incision of the drum, extending from the posterior lower quadrant up to the attic under direct vision, using the ear instrument previously described. A rapid fall in temperature and alleviation of symptoms should follow. Repeated incisions should be made, if necessary, for free drainage, but it should be remembered that obstruction of the Eustachian tube in the throat may prolong a discharge from the ear. In infants etherization is not necessary, but in older children enough ether should be given to allow time for a careful and accurate incision. The other ear should be watched with special care as a double otitis is frequent.

CONCLUSIONS.

In every case of contagious disease and of affections of the respiratory tract in children, measures should be inaugurated at once to keep the nasopharynx clear and so maintain drainage through the Eustachian tube. In such cases the ear drum should be inspected at every visit of the physician to his patient.

An electric ear instrument gives a clear picture of the drum with a minimum disturbance of the child.

In cases of otitis media when the symptoms and the local condition do not improve under treatment the drum should be incised by the aurist, if available, otherwise by the attending physician, without waiting for bulging or pus.

Every child, after an attack of acute otitis media, should have his epipharynx examined and treated by a specialist trained to recognize the close relation of the nasopharynx to the ear.

CAN THE SPEECH PRESENT A SIGN OF CONGENITAL SYPHILIS?*

FIRST NOTE, THREE CASES.

BY WALTER B. SWIFT, M.D., BOSTON,

Instructor in Neuropathology, Tufts College Medical School; In Charge, Voice Clinic, Boston State Hospital, Psychopathic Department.

I MAKE no apology for presenting a paper before a scientific society in the form of an interrogation rather than in the usual form of a positive statement. My reason for doing so is threefold: First, I lack the clinical material to carry the investigation on to the final stages; secondly, I wish to inspire others to undertake the observations themselves; and, thirdly, I may possibly be able by this form of presentation to divert a few cases to my own clinic for investigation.

Several of the many varied symptoms of congenital syphilis show certain definite characteristics. One of these is "Hutchinson's teeth." This sign of congenital syphilis is one that we usually expect. It is a failure in complete bone development; that is, it is the result of a nutritional lack which stops the final outgrowth of bone. This symptom itself is usually looked upon as strongly indicative of the syphilitic lesion. It is not pathognomonic.

Most of us have heard of the malnutrition of bone and regard that also as another strong indication. This symptom, which is known as scaphoid scapula and which has been presented by Graves¹ of St. Louis, is another lack of bone growth that may be caused by syphilis in its congenital form. Graves acknowledges that this symptom is not one which is pathognomonic of the lesion in question, yet it nevertheless can be caused by it. He therefore would base a diagnosis upon the existence of other signs of the same kind; and when this one is present with the others, he considers that it, too, has been caused by the syphilitic infection.

"Hutchinson's teeth" are found by simple observation. The scaphoid scapula is determined by palpation or through the employment of an x-ray. Any sign that the voice may present is naturally detected by the way the voice sounds to the ear. Thus if there is any sign in congenital syphilis that appears in the voice, it will naturally be one that without further examination can be detected acoustically. Inspection of the vocal cords should follow.

Several interesting cases which have come under the observation of the Voice Clinic at the Psychopathic Hospital have led me to ask my question. The chief of these is the appearance of three congenital syphilitic cases with voices of similar nature. Those cases I should like to present in very brief form:

CASE 1. E. W., girl, 10, Russian, school grade 6. Complaint: hoarseness.

* Read April 30, 1915, before the New England Pediatric Society.

P. I. Voice has never been clear. For the last year considerably worse. Very hoarse when crying.

P. H. At 8 months, diphtheria; at three years, measles. Nose once broken. One year ago tonsils and adenoids removed. Promised voice cure that never materialized.

F. H. Father and mother living and well.

P. E. Negative except for scaphoid scapulae and deeply notched upper incisors (Hutchinson teeth). No tibial extoses. Wassermann positive.

Vocal Examination: Vocal elements all normal except S, which shows slight right lateral stigmatism. Vocal tone is in general very monotonous and on a pretty constant low pitch. On attempt to sing the scale beginning at C' (256) the last two or three notes are hard to execute, ill-sustained, and often break. Voice tires quickly, especially upon high notes. Had a peculiar "tinpany" cry when a baby.

CASE 2. S. B., boy 10, school, Russian.

P. I. Complaint: Lips and talks in a whisper. Began to talk by lisping; and by saying his words in a whisper. Now converses in a rough, rasping, harsh voice. Used also to stutter, but now shows no sign of it.

Vocal Examination: Fricatives and explosives all normal. No stutter. Every utterance accompanied by a vocal cord rasp, giving a certain uniform hoarseness. Whisper is clear in all forms of enunciation. Edges of both vocal cords are thick, white and hardened. Right vocal cord markedly bowed outward. That is, the finer edges are absent.

P. H. Four-five, measles; nine, adenoids and tonsils.

F. H. Immediate family negative. A cousin "insane."

CASE 3. C. N. Scaphoid scapulae.

Hoarse since birth. Father same.

Heart misses a beat in every four. Otherwise negative.

Wassermann positive.

In these three cases congenital syphilis was our diagnosis.

All these cases presented a certain type of voice which has the following characteristics:

SYPHILITIC TYPE OF VOICE.

The characteristics that were noticeable were a harsh, squeaking, monotonous tone, noticeably intense, a considerable tenseness of the vocal organs, absolutely no flexibility and little or no change in pitch. Besides these things, after treatment though long-applied, persistent vocal drill, only slight changes, if any, resulted.

The failure of any treatment and the consequent impossibility of adding any flexibility to such a voice naturally gave rise to the conclusion that the organs of production were permanently changed. The evidence further showed that the change was not only permanent but marked. It was such that the vocal cords could be used in only one way; and this without any possibility of development, variation, or learning ability—a functional incapacity.

Beyond showing the permanency of this change, the vocal sounds indicated the kind of change, as well. It was monotony of voice, or, in

other words, a lack of flexibility. This logically indicated that the edges of the vocal cords were immovable, rounded and hardened. For this reason minute vibrations could not occur, and a change of pitch was out of the question. Consequently a variation in tone that would otherwise be flexible was also impossible.

From the character of the sound, then, and from the monotony of it we are able to infer that the change is permanent; and that it was either a thickening or hardening of the edges of the vocal cords, or, better, a lack of development in the edges of those vocal cords. Inspection confirmed this diagnosis.

I have been unable to photograph any of these cases so as to show you how the vocal cords are hardened, but I think we may come to some tentative conclusion even without that evidence. My question, then, is this: If we can have a syphilitic infection that results in the non-development of a certain area of the two upper frontal incisors; and if in the same manner we can have a lack of bone development in the scapulae that can result in a marked deformity, and a deformity so marked that it can be dignified with the new name, scaphoid scapulae; why can we not likewise have such a mal-formation of the cartilages of the vocal cords that those cartilages will be unable to function in their finer forms and can merely externalize voice as a harsh, rasping, monotonous tone?

He who meets continually the individual cases often has a chance to see conclusions that others can not draw from the words. I feel that I am in that situation, yet I do not feel that the conclusion which I draw is as final as more evidence in further investigation will be able to make it. I should remind you that perusal of the literature reveals no description of this sign.

CONCLUSION.

I conclude from these three cases that there is a voice sign in congenital syphilis which manifests itself in a harsh, rasping, monotonous, low-pitched voice that is at most only slightly, and usually not at all, amenable to any sort of treatment. I bring the question up as a point of discussion to be taken up by you and threshed out in still better form. I trust either that my question will elicit markedly destructive data to settle the query in one way; or that the discussion will present fuller and clearer evidence than I have been able to find, and that corroborative criticism may more completely establish my conclusion. My answer to the original question is positive.

SUMMARY.

Congenital syphilis can cause a faulty or incomplete development of vocal cords that results in vocal monotony and harshness in both conversation and weeping. As spirochaetosis has

been of late offered² to cover all the lesions of syphilis. I propose as a name for this sign *scaphoid vocal cords and spirochaetotic harshness*.

Clinical Department.

AN UNUSUAL CASE OF OBSTRUCTING PROSTATE DIAGNOSTICATED WITH DIFFICULTY FROM TABES.

BY J. DELLINGER BARNEY, M.D., F.A.C.S., BOSTON,

Genito-Urinary Surgeon to Out-Patients, Massachusetts General Hospital;

AND

JAMES B. AYER, M.D., BOSTON,

Assistant Neurologist, Massachusetts General Hospital.

IN the belief that we learn by our mistakes, and that the ultimate solution of any difficult problem in differential diagnosis may be of benefit, not only to the individual physician, but to the profession in general, we wish to present the following case:

CLINICAL SUMMARY:

A. M., a man of 42 years, had been absolutely well, with the exception of one attack of gonorrhea in youth, until six months previous to December, 1914. He then began to have difficulty and increasing frequency of micturition with incontinence at night. No retention. Had passed no blood or gravel. There had been no pain, but a sense of burning at the beginning of micturition. Had also had considerable dull pain in the lumbar region, especially on the right, but no symptoms especially referable to the kidney. No nausea or vomiting.

He had lost 25 pounds weight in the six months. For four months his sexual power had been decreasing and of late there has been none at all.

Further inquiry found no symptoms referable to the nervous system, especially important in connection with a possible diagnosis of tabes, though the patient admitted transient diplopia a number of years ago. He denied syphilis, though his wife had had five "accidental" miscarriages since the birth of two healthy children.

Physical Examination. A pale, emaciated man. Looks weak and sick. Superficial arteries not thickened. Blood-pressure 130 m.m. systolic, 75 m.m. diastolic. Tongue moist, slightly coated. Lungs negative. Heart shows systolic and diastolic murmurs over the aortic area, presumably originating from the aortic valve; the pulse suggesting the Corrigan type. No evidence of a dilated arch. Abdominal examination negative, except that urinary bladder is greatly distended. External genitals negative.

Patient passed about five ounces of cloudy urine

and felt "as if he had more to pass." Urine acid, would not filter clear, very slight trace of albumin, no sugar. Sediment showed much pus, few epithelial cells, many motile bacilli. No blood, casts or crystals seen. Calibration of the urethra showed no stricture. A soft rubber catheter passed easily to the bladder, withdrawing (on several occasions) 18-20 ounces residual urine. *The prostate by rectum was normal in size and consistency.* The seminal vesicles were considerably distended, but not indurated.

With no evidence of stricture of the urethra, or of prostatic obstruction, a cystoscopy was done (J. D. B.). This was easily performed under local anesthesia (alypin). There was no pain or intolerance. The bladder was generally reddened, but the mucosa was smooth, and not edematous, or ulcerated. The bladder wall throughout was markedly trabeculated, a characteristic of obstruction, not only of mechanical, but of nervous origin.* The ureters looked normal. A No. 6 flute-tipped catheter passed easily to each renal pelvis, there being a good flow, in normal ureteric rhythm, of clear urine from each side. *No enlargement of the prostate could be made out.* High up on the right wall there was seen a round opening, the size of a dime, like that of a diverticulum, but a ureteral catheter would enter for only about half an inch.

While the diagnosis was still in doubt there was some evidence of the presence of a diverticulum (which might well have occasioned the bladder symptoms) a possibility borne out by the fact that when the bladder was filled there was an indefinite, rounded, tender mass to be felt deep in the right iliac fossa.

X-ray of the bladder, distended with air, showed it to be conical in shape, with the apex drawn well over to the right side, undoubtedly giving rise to the findings already described.

In view of the obscure nature of the case, and the absence of any demonstrable mechanical obstruction, a careful examination of the patient's nervous system was made (J. B. A.). There was no abnormality of reflexes, although the pupils were both irregular, but equal, reacting fairly well to light, better to accommodation. No disturbance of sensation, superficial or deep. No Romberg or difficulty in gait. No palsies. Laboratory tests were performed with the following results.

Blood. Wassermann, negative (even with cholesterin reinforced antigen). A Wassermann test done later on the wife's blood was also negative.

Stained Smear. Normal.

Spinal Fluid. Pressure 210 m.m. (aq.); cells one per cmm.

Proteids not increased.

Gold Solution. "Suspicious of syphilis." (Report of laboratory at Massachusetts General Hospital.)

The diagnosis, therefore, lay between an early and obscure affection of the central nervous system, and a diverticulum of the bladder, but there was no adequate basis for either diagnosis. The possibility of an obstructing prostate was practically disregarded. As there was little or no change in the ability of the patient to empty his bladder, even after several days in bed and with frequent catheterization, operation was decided upon. This decision was reached only after careful deliberation, and the tentative conclusion that syphilis of the central nervous system

could be excluded. The daily amount of urine was well over 50 ounces.

Operation. (J. D. B.) Spinal anesthesia with tropococain 1.5 c.c., a little ether being given to offset the extreme mental excitement. Suprapubic cystotomy. Bladder opened without difficulty. Careful exploration showed no diverticulum, the aperture on the right wall of the bladder seen with the cystoscope being only a saucer-like depression. Bladder wall much thickened and trabeculated throughout. Median lobe of prostate found to be the size of the first joint of a man's thumb, overhanging the urethral orifice, and acting like a ball-valve. This was enucleated without difficulty, and no other masses of adenomatous tissue were found. The bladder was closed tightly around a large, soft rubber tube, a small rubber tissue wick was placed to the prevesical space, and the abdominal incision was closed in layers.

Microscopic examination of the enucleated specimen showed simple adenoma.

Convalescence was uneventful. The patient has recently been seen by one of us (J. D. B.) on two or three occasions, six months after operation. He has gained 15 or 20 pounds and is in good general condition. His appearance is that of perfect health. The condition of the sex function is unchanged. Urination is painless and free, occurring only four or five times a day. There is no nocturia. The urine is practically clear, and there is no residual whatever.

SUMMARY AND DISCUSSION OF DIAGNOSIS.

A man of 42 presents a progressive motor disability of his bladder, coupled with loss of weight and sexual power, of six months' duration. Local examination fails to reveal an adequate cause. The negative examination for bladder obstruction, the finding of a trabeculated bladder mucosa, the associated loss of sexual power, irregular pupils, reacting poorly to light, evidence of disease at the aortic valve, combined with the history of five miscarriages in the wife, make strong evidence for the diagnosis of syphilis and of spinal cord disease. On the other hand examination of the nervous system fails to show any supporting evidence in favor of the latter, and tests are found negative for active syphilis (the "suspicious of syphilis" report from the "gold test" is not to be taken too seriously at the present state of our knowledge of this test).

While it is our conviction that bladder retention may be the first and for some time the only clinical symptom of tabes, as already pointed out by one of us (J. D. B., *loc. cit.*), it is also our experience and belief that progressive bladder retention is probably never the sole manifestation of this disease. One or the other of the newer laboratory tests will reveal the true nature of the case. Therefore, in view of the negative findings in the nervous system, but more especially on account of negative findings in the spinal fluid, tabes was excluded and operation advised.

This case is cited in full on account of the diagnostic maze through which the true diag-

* Barney: BOSTON MED. AND SURG. JOUR., Vol. cxxiii, No. 25, pp. 933-937.

nosis emerged and was forced upon us, largely on account of reliance upon the newer laboratory tests. While it is hard to understand how a lobe of the prostate, as large as the one removed from this patient, could escape detection by the cystoscope, such an experience is not unique. One of us (J. D. B.) has since had a similar case in which the enlarged median lobe was demonstrated only after repeated observation with the cystoscope. The soft, pedunculated lobe, hanging over the urethral orifice, like a cherry on its stem, may be flattened down by the cystoscope in such a way as to escape observation.

REPORT OF AN INTERESTING STOMACH CASE.

BY FRANK E. LEWIS, M.D., NEWTON, MASS.,

AND

RALPH D. LEONARD, M.D., BOSTON.

This case is reported not alone for its surgical aspect but also for the fact that it shows the inestimable value of the x-ray in the diagnosis of obscure cases of stomach conditions.

Marg. C. was seen October 3, 1914. At this time she gave the following history: Single, 39 years of age. Vocation, domestic.

F. H. Negative. No history of cancer or tuberculosis.

P. H. No serious illness until 1904 when patient had typhoid fever followed by pneumonia.

P. E. Patient slight of stature, anemic and markedly emaciated. Weight, 90 pounds. Pupils react to light and distance. Fundi normal. Teeth in fair condition. Breath very foul. Mucous membrane pale. No glandular enlargement. Lungs resonant throughout. Heart sounds clear and regular. Level of the abdomen below that of the thorax. Slight tenderness and resistance in the epigastric region. No masses felt. Vaginal examination negative. Reflexes normal. No edema of the extremities.

P. I. Present condition dates back to 1905 when patient first began to be markedly constipated. This condition was accompanied by occasional vomiting. In the fall of 1906 patient had a typical epileptic convulsion during which patient vomited a large amount of material with an offensive odor. Since 1906 these attacks have occurred on an average of twice a month. The vomiting which at first was only occasional became a more pronounced feature until finally the patient was vomiting regularly 30 to 40 minutes after each meal (Aug., 1914). The only pain noted was a slight burning sensation that came on just before vomiting. Patient said she noticed that the stools had been dark in color during the last few months. Never noticed whether there had been any blood in the vomitus. Appetite has been getting poor and patient has lost a great deal of weight.

Urinalysis. Sp. Gr. 1020, no albumen, no sugar, acid in reaction, marked indicanuria. Blood examination showed a secondary anemia. Positive Guaiac test obtained from the stools and vomitus. Stomach contents showed a slight increase in hydrochloric

acid and a small amount of stasis. Wassermann negative.

Patient was advised to have x-ray examination of the gastro-intestinal tract. Following is the report of the röntgenologist:

REPORT OF THE RÖNTGEN EXAMINATION MADE OF MISS C.

Esophagus. Appears normal in all respects. There is no "hesitation" at the cardia.

Stomach. Under the fluoroscopic screen, there is seen on the lesser curvature, mid-way between pylorus and cardia, an area of "rigidity" about an inch and a half long. Normal peristaltic waves do not affect the outline of this area nor can the area be moved by palpation. Opposite, on the greater curvature is a permanent incisura, producing a typical hour-glass stomach. There is no marked gastric stasis.

Roentgen Picture.

Showing:

- (1) High gastric ulcer.
- (2) Duodenal ulcer with perforation.

Duodenum. On the upper and inner edge of the first portion of the duodenum is a small diverticulum about one-half inch in diameter. The isthmus forming the neck of the diverticulum and opening into the duodenal "cap" is about three-quarters of an inch in length with a diameter of a thread. Opposite on the outer and inferior edge of the "cap" we find a small permanent incisura.

Small Intestine. Shows nothing abnormal save that the upper coils of jejunum overlie the antrum of the stomach and the first portion of the duodenum. These coils are fixed in this position.

Colon. Shows nothing abnormal except moderate ptosis.

Diagnosis. Chronic gastric ulcer on lesser curvature with hour-glass stomach. Chronic perforated duodenal ulcer with adhesions tying down some of the jejunum.

The diagnosis having been made, the patient was advised to have an operation, to which she consented.

Patient entered the hospital Oct. 14, 1914, one week before operation. The bowels were thoroughly

cleaned out with daily enemata and catharsis. The stomach was washed daily with borie solution. Intravenous saline was administered the day before operation.

Operation Oct. 20, 1914, Fred B. Lund, M.D., and Frank E. Lewis, M.D.

Abdomen was opened by a high, left median incision. Contrary to expectation, the stomach was found to be fairly movable. There were many dense adhesions on the posterior part of the stomach which were not freed. The stomach itself was of the textbook "hour-glass" type, the isthmus between the cardiac and pyloric portions being very narrow. On the lesser curvature was a hard, rigid area, evidently a healed ulcer. Opposite to this on the greater curvature was a deep incision. The pylorus was soft and patent, two cm. from the pylorus on the duodenum was a mass of adhesions, evidently the place mentioned in the x-ray report. The appendix was normal. A posterior gastro-enterostomy was performed between the cardiac pouch of the stomach and the upper part of the jejunum. The constriction between the pouches of the stomach was relieved by a plastic operation which included the excision of the ulcerated area. In this last step vigorous hemorrhage was encountered and the patient's condition became alarming. The stomach was washed out thoroughly with saline and the abdominal wound closed. Profound shock followed the operation for the first twenty-four hours. After this, however, the convalescence was uneventful.

RESULTS.

Since the operation the patient has had no vomiting and the epileptic fits, which were such a prominent feature, have entirely disappeared (May, 1915). One of the best features is the relief from constipation. The patient's weight which was 90 pounds at the time of operation is now 114 pounds.

Reports of Societies.

NEW ENGLAND PEDIATRIC SOCIETY.

MEETING OF APRIL 30, 1915, WAS HELD AT THE BOSTON MEDICAL LIBRARY.

The President Dr. E. M. BUCKINGHAM of Boston, in the Chair.

The following papers were read:

I. CAN THE SPEECH PRESENT A SIGN OF CONGENITAL SYPHILIS?

W. B. SWIFT, M.D., Boston.

II. ACUTE OTITIS MEDIA IN CHILDHOOD: AVOIDABLE MISTAKES IN DIAGNOSIS, PREVENTION, TREATMENT.

W. R. P. EMERSON, M. D., Boston.

III. STUDIES IN BRONCHIAL GLANDS.

W. W. HOWELL, M. D., Boston.

IV. ENDOCARDITIS IN CHILDREN: ITS PROPHYLAXIS AND TREATMENT IN AN OUT-PATIENT DEPARTMENT.

R. S. EUSTIS, M. D., Boston.

¹ See JOURNAL, page 619.

² See JOURNAL, page 616.

³ See JOURNAL, Vol. CLXXIII, No. 10, September 2, 1915.

DISCUSSION.

DR. W. P. CONES: Among the symptoms which Dr. Swift did not mention and which one sees from time to time are the large, soft, dilated veins on the abdomen and chest; another is the saw-line of the epiphyses, both of which are not absolutely diagnostic, but very suggestive. I think that Dr. Swift's paper brings up also the question of third generation syphilis which most American syphilographers do not admit, or at least admit very guardedly as being possible. To those who are skeptical on this subject, the perusal of Fournier's recent book, 1912, "Late Hereditary Syphilis of the Second Generation," will be a revelation.

I was very much interested to see that the Wassermann in this case was doubtful, as we have had in our clinic several cases of the same sort. Some cases have shown gumma of the glands of the neck, and this is a point which we do not always think of.

Question: May I ask if the hoarseness is permanent and does not change?

DR. SWIFT: Yes.

DR. WALTER B. SWIFT (closing): I am glad so many have taken interest enough to discuss my paper. I regret, however, that Dr. Post could not return from Buffalo in time. He holds that the clinical side of syphilis still needs working up in researches and should not be neglected for the serological side. He believes in my voice sign in congenital syphilis and considers it a symptom of some value.

I notice no dissenting in the discussion this evening, no one has offered any evidence that undermines this claim of a speech sign in hereditary lues. As far then as a preliminary note, though as yet unconfirmed, it stands unattacked.

In answer to Dr. Solomon, I would say a word about frequency. Of course, I have not had enough cases to establish any frequency. These other signs, Hutchinson's teeth, tibial exostoses and interstitial keratitis all have their relative frequency. A matter can be established only by having a large number of cases and making a thorough examination of every point in each.

In response to Dr. Cones I would say that it was not my purpose to be exhaustive in the presentation of symptoms. He seems to know them all! I merely present at this time what I consider as evidence enough to establish a voice sign as a new symptom.

In response to Dr. Brown, I would thank him for participating in the discussion and presenting his valuable data. I wish you all had said more to undermine my claim. It is unfavorable criticism I like best. We learn most from that.

That speech alone should have brought these patients to the Voice Clinic is significant. It shows that the speech was the one organ affected in a marked way. It shows that the speech sign was the only one noticeable. It shows that here we may have a new and easy avenue to finding syphilis in parents; and thus lead to steps of prevention not otherwise approachable.

Some may feel that the functional evidence I offer is not sufficient. I would add a word to refute this.

When in Berlin I presented my temporal lobeless dog to the Berlin Neurological Society some one objected that I had not offered anatomical proof. My chief, Professor Jacobsohn, then arose and said, "The functional evidence is sufficient." So here, the monotony, the harshness, and the low pitch in

incurable forms, are conclusive evidence of permanent structural change.

I consider the speech mechanism as the easiest avenue to the earliest symptoms of many a nervous and mental change. But we are not yet quite sensitive enough to catch this message! This paper is one of a series of contributions to this early aspect of mental hygiene, which will aid in diagnosis of vague cases in the interest of prevention. Let me emphasize again that the hope along the line of prevention is that this sign may show up some syphilitic cases that would otherwise remain unknown. It has already done so in the cases mentioned above. Once this voice sign is known and through practice can be easily recognized merely by listening, it then will be a key not only to the case in hand with brothers and sisters but to parental conditions as well.

ACUTE OTITIS MEDIA IN CHILDHOOD; AVOIDABLE MISTAKES IN DIAGNOSIS, PREVENTION, TREATMENT.

DR. BORDEN: I heartily endorse all that Dr. Emerson has said, and I am very pleased to hear the subject presented by somebody other than an aurist. It is a very important subject, more important I believe, than many of us realize. There are several points which I would like to mention which go beyond the range of Dr. Emerson's paper. It is a well known fact that pus under pressure is much more virulent than when it is unconfined. In the event of a middle ear abscess, we have this condition of pus under pressure well illustrated by the elevated temperature. The temperature remains high as long as the tension is maintained. When paracentesis is performed or the pus finds its way back into the mastoid the temperature usually falls. This fact has led me to do some rather radical operating at the Somerville Hospital during the past two years. At this institution, we have come to the conclusion that diseased conditions of the middle ear or mastoid, if very acute, are not infrequently the primary cause of complications in the heart, lungs, joints or kidneys. This theory will doubtless seem to you to be very far fetched, but we are able to prove in some six or eight cases of acute nephritis opening the mastoid cavity was speedily followed by marked relief in the inflamed kidneys. All the cases mentioned had a rather high temperature at the time of operation, but each case showed no harm as the result of the anesthetic or of surgical shock. Several other cases in this institution have been conspicuous examples of the middle ear or mastoid being foci of infection. These were cases of over prolonged convalescence. Two such cases were operated upon by opening the mastoid cavity. The only symptom of an aural nature was a chronic discharge. When the mastoid was opened in one case the entire mastoid cavity was found to be filled with pus and granulations and the lateral sinus was exposed for more than half an inch. In the other case the entire mastoid was sclerotic, but the roof of the middle ear and antrum was wanting, and the dura covered with granulations. In both cases, the general conditions of the two patients improved remarkably immediately after the operation.

Dr. Emerson has mentioned the curved incision in performing paracentesis. In my opinion, there is no necessity for a curved incision. All the talk about such a fancy surgical procedure has kept many physicians from opening distended drums when it was greatly to the patient's advantage to

have the relief from pressure. I realize that this is the rankest kind of heresy from the standpoint of an aurist, but I have seen a great many so called curved incisions become the ordinary pin point opening within twenty-four hours, and I have never seen one remain a curved opening for any length of time. Hence, a straight opening made as large as is consistent with safety will do as well.

The so-called nipple-perforations of the ear drum membrane are important things to recognize inasmuch as they are the conditions which are most liable to cause future deafness. They consist simply of weak areas in the membrane and unless vigorously dealt with, slough out and leave large permanent openings. These are the cases which we see in our offices with deafness dating back to scarlet fever and measles in childhood. Nipple perforations are most common when there is a tremendous discharge from the ear. Occasionally, they occur when there is no discharge present. They may therefore occur at any stage and their presence is always a menace to the future welfare of the hearing apparatus. When a physician is called upon to care for a patient having middle ear disease, either alone by itself or as a complication of another disease, he assumes not only the responsibility of the patient's present illness, but the future of the organ of hearing as well.

DR. J. L. MORSE: Everyone who sees many children will agree heartily with what Dr. Emerson has said. One or two points were suggested to me, however, while he was talking. I think that almost everyone is inclined to be too hopeful as to the immediate results of opening the ears. One is likely to tell the family that the temperature will come down immediately, and that the child will be well in a few days. This is true in many instances, but in more it is not. The temperature remains up, or even goes higher after the ears are opened, and the family and often the physician feel positive that there must be something else the matter. It is a mistake to expect immediate benefit from the opening of the drums in every case. I have also been impressed with the duration of the symptoms in many instances before the appearance of any definite signs in the ears. The child will be sick for several days and in the absence of any symptoms or signs elsewhere it will seem almost certain that the trouble is in the ears. Finally, signs in the ears will develop, to be followed by the relief of symptoms when the ears are treated. In other cases the signs in the ears develop very rapidly, sometimes in the course of a few hours. In other instances they will disappear as rapidly. Everyone who is honest will admit, I think, that it is very difficult to see the drums in many babies under a year old. This is especially true when the drums are inflamed. In many instances it is impossible to know exactly where the drum is to be punctured. It is simply a question of making a cut where the operator thinks it should be made.

DR. EMERSON, in closing: My experience has been such that in speaking of an otitis media, I hesitate to use the word "simple," as pathologically there may be oedema of the brain with only a slight congestion of the drum membrane. I recently saw a child with perforation into the external canal and the ear drum appeared normal.

On inquiring about, I find that most physicians do not examine the ears at all. In the past few days I have asked five surgeons and five physicians, all on the staffs of our large hospitals, as to whether or not they carried with them any means of examin-

ing the ear. The surgeons all answered in the negative, one offering me his head mirror if I wanted it, saying he was quite sure he had one in his office. Of the medical men, three did not carry in their bags any means for examining the ears, the 4th carried an ear speculum because he had had an ear service as an house officer in the hospital, and was especially interested. The 5th had carried an ear speculum for the past year, since having a child very ill with an unrecognized otitis.

STUDIES IN BRONCHIAL GLANDS.

Abstract: Dr. Howell studied the cases coming under his care during the past year to determine the frequency of bronchial adenitis, the reliability of the signs and the possible pathology of the glands. The cases were from the Infants' Hospital, a large school, and private practice, about one thousand in all. The age limit was thirteen years.

It was found that the D'Espine sign varied with age, below the second dorsal in infancy, at the second dorsal at six years, at the first dorsal at twelve years, and often found as low as the third dorsal at all ages. Hence, no case was considered positive if not at or below the third dorsal.

The glands were divided into two groups, those along the trachea and those at the root of the lungs. The tracheal group was enlarged by infection entering carious teeth, adenoids and tonsils. They gave positive D'Espine but no dullness. The glands at the root of the lungs were enlarged from an inflammation out in the lung and gave both positive D'Espine and interscapular dullness, and in this series was usually tuberculous.

Dr. SMITH: I was very much interested in Dr. Howell's paper, because for some time I have been working along the same line. It seems to me that an important point has been brought out by everyone, namely, that there are many other chronic conditions that give enlarged bronchial glands besides tuberculosis. The most valuable single sign of enlarged glands to me is dullness at the lung roots, best elicited by percussion between the scapulae. This is more consistently reliable than the D'Espine sign or dilated veins, or change in the character of the voice. I think that the direction of the dullness from the area into the rest of the lung is of some value in differential diagnosis. A tuberculous process involves the apices early and when, together with the dullness at the lung roots there is also dullness in one or the other apices, it is probable one is dealing with a case of tuberculosis, but when the apices are clear one ought to be very cautious about making a diagnosis of tuberculosis.

Dr. F. B. TALBOT: Dr. Howell's paper has interested me very much, and I agree entirely with what he says. I would like to add, however, that I have been confused several times by x-ray pictures which apparently show an enlarged thymus, as in one instance in which post-mortem examination proved to be enlarged bronchial glands. My experience, also, has added other diseases than tuberculosis to those which may have enlarged bronchial glands. Among them are whooping-cough, and measles during the acute stage and chronic influenza of the lungs.

Dr. BOWDITCH: I am interested in what I understand Dr. Howell calls the normal D'Espine sign, as I have somehow or other arrived at the same conclusion. It has seemed to me to be a spot at the point where the line of the spinous processes of the

vertebrae, and a line between the spinous processes of the scapula cross each other. This is about the third dorsal vertebra. At this spot I have usually found the change described by D'Espine. I was much interested in Dr. Howell's findings, and I agree most heartily with the points which Dr. Howell brought out.

Dr. J. L. MORSE: It seems to me that one of the most important things that has come up this evening is the doubt which has been shown as to what D'Espine's sign is. D'Espine's sign, as he originally described it, is the persistence of the bronchial whisper through the seventh cervical spine. Others have claimed that the bronchial whisper is normally present through the second or even the third dorsal spine. I have examined every child that I have seen during the last two years in relation to the presence or absence of D'Espine's sign. A large proportion of these children were seen in private practice. In a great many of these children the change in sound occurred between the seventh cervical and the first dorsal spines. My feeling is, therefore that D'Espine was right in his original description of the sign. I do not feel sure that it is abnormal to have the bronchial sound persist through the first dorsal spine, but am positive that it is abnormal if it is heard lower than this. D'Espine's sign is very seldom found in good private practice. It is present, however, in a very large proportion of the children belonging to the hospital class, whether they are seen in the out-patient department or in the wards. I am somewhat surprised at the comparative frequency with which some men have found dullness over the vertebrae and in the interscapular space. I have often found what I have called a positive D'Espine sign when I have not been able to demonstrate interscapular dullness or dullness under the spinous processes.

Dr. HOWELL, in closing: Dr. Talbot in his remarks brought up the question of whooping cough. I did not include a series of whooping cough in this paper because I thought it would make it too long. I had the opportunity to examine about 30 cases in a private school not long ago, and the results were rather interesting. The exposure was pretty definite and the incubation time about normal. Some of the findings were as follows: No case developed a whoop until there was a positive D'Espine's sign, and there was no case in that series with interscapular dullness without signs in the lungs; the whooping did not altogether disappear with the disappearance of the D'Espine sign. Two cases with definite exposure, a bad cough, and lymphocytosis never developed a positive D'Espine sign, the symptoms suggesting that the whoop might be connected with thickening of the trachea. I do not mean to imply that all cases with a positive D'Espine's sign with definite signs in the lungs should be called tuberculosis, but I have been surprised to find the number of such cases which prove to be tuberculous. Since then I have looked for this sign in every child examined, and I have come to the conclusion that it is a very important sign in infants under two years. I also do not mean to imply that the D'Espine sign alone is of much value. I think it is caused by slight changes in the glands up and down the trachea, as well as by definite thickening at the hilus. I have seen cases of chronic influenza and chronic bronchitis with positive D'Espine's sign and some of these cases had a positive Von Pirquet besides, but in my opinion it is better to treat these cases as if they were tuberculosis.

ENDOCARDITIS IN CHILDREN; ITS PROPHYLAXIS AND
TREATMENT IN AN OUT-PATIENT DEPARTMENT.

DR. TALBOT: Dr. Eustis has presented this paper in a very modest way. He has spent a good deal of time and energy in the work and he has told me privately that his results were a great deal better than the paper shows, and my opinion, after seeing the individuals occasionally, is that he has accomplished a great deal more than his figures show. This preliminary report is to attract attention to the methods of handling endocarditis in an out-patient clinic.

Book Reviews.

The Clinics of John B. Murphy, M.D. At Mercy Hospital, Chicago, February, April, June, 1915. Philadelphia and London: W. B. Saunders Company. 1915.

Each of these three volumes begins with Dr. Murphy's "Clinical Talks on Surgical and General Diagnosis."

In the February volume there is a series of articles upon fractures and dislocations, and a characteristic talk on appendicitis. Dr. Murphy says that pain, nausea, vomiting, elevation of temperature and tenderness in the right lower quadrant appear "early and usually in the order named." He formerly taught that this order was invariable.

In the April number are interesting articles upon carcinoma, hypertrophy of the prostate, arthroplasty of the hip. Dr. William L. Rodman of Philadelphia contributes one of the talks on carcinoma.

In the June number there is another talk on appendicitis, and a number of other chapters upon the following subjects: intestinal obstruction due to a large gall-stone; painful exostosis of the os calcis; chronic tendo-vaginitis of the extensor tendon of the thumb; tumor of testicle; technic of laminectomy; and a talk on unsuccessful gastro-enterostomy for ulcer, by William J. Mayo. The illustrations in the June number are even better than the average, and the average has always been high.

The Treatment of Fractures. With Notes upon a Few Common Dislocations. By CHARLES LOCKE SCUDDER, M.D. Eighth edition, revised, with 1057 illustrations. Philadelphia and London: W. B. Saunders Company. 1915.

This eighth edition of Dr. Scudder's book is a volume of more than seven hundred pages, and is illustrated with ten hundred and fifty-seven pictures. The book maintains entirely its pre-

vious form and scope. Those who have enjoyed it before will find it still more to their liking.

It seems, however, that the detail of the operative treatment of fractures is not as full as might be desired. This is true, notwithstanding the fact that Dr. Scudder believes "operative treatment is not to be undertaken lightly." There is a disproportionately small amount of space allotted to operative treatment; an examination of Chapter XVI shows that it occupies less than ten pages, more than one-half of this space being given up to illustrations; the actual type under the heading of "The Method of Operating upon the Shafts of the Long Bones" is less than three printed pages.

There is no doubt that at present a great deal of unnecessary and inadequate work is done (and too often by poorly trained surgeons), in the operative treatment of simple or closed fractures; yet in reality this makes it the more desirable that the precise detail of the operative technic should be put down with much elaboration in a text-book of this character, which is so popular as to require either a new edition, a revision or a reprinting practically every single year since it first appeared in 1900. The illustrations are admirable, and the press work equally good.

Diseases of the Digestive Organs. By CHARLES D. AARON, Sc.D., M.D. Philadelphia: Lea and Febiger. 1915.

Dr. Aaron disses in his book of 750 pages the diagnosis and treatment of all pathological conditions of the digestive tract from the mouth to the anus. The book finds ample justification in the rapid strides that have been made in the diagnosis of abnormal conditions, particularly of the stomach and intestines. The author gives in careful detail directions for performing all the usual diagnostic tests and many of the unusual ones. His careful description of these tests is one of the most valuable features of the book. As a matter of course much reference is made to the Roentgen ray and a number of Roentgenograms are reproduced. Many workers will not agree with his implicit faith in the diagnostic accuracy of the Roentgenograph. For example, he states that "Roentgenographically about 40% of gall stones can be diagnosed." The author speaks with enthusiasm also of the use of electricity in the treatment of gastric and intestinal disorders. A certain positiveness of statement such as "all patients suffering from gastroenteroposis require iron in some form," detracts somewhat from an otherwise sound discussion. He also speaks of the value of bacterial vaccines and phylacogens in the treatment of appendicitis. On the whole, it is a careful and complete work, accurately compiled, and well indexed and should serve as a valuable book of reference in the diseases of the intestinal organs.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, OCTOBER 21, 1915

EDITORS.

ROBERT M. GREEN, M.D., *Editor-in-Chief.*

GEORGE G. SMITH, M.D., *Assistant Editor.*

WALTER L. BERRAGE, M.D., } *For the Massachusetts Medical Society.*
FREDERICK T. LORD, M.D., }

COMMITTEE OF CONSULTING EDITORS.

WALTER B. CANNON, M.D. ALLAN J. McLAUGHLIN, M.D.

HARVEY CUSHING, M.D. ROBERT B. OSGOOD, M.D.

DAVID L. EDSELL, M.D. MILTON J. ROSENAT, M.D.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

The editor will be in the editorial office daily, except Wednesday and Sunday, from one to two-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

FEE-SPLITTING.

It is with no purpose of airing soiled linen in public that we advert on certain evil practices that obtain among a small minority of those who practice the healing art. Although the medical profession consists for the most part of high-minded ethical practitioners, there are within its ranks, just as in other professions, men holding to various standards of right and wrong. To a young doctor in the early years of practice, struggling to make a living at the beginning of that long journey to eminence and fame, substantial fees offered by an apparently successful practitioner for attendance on cases of induced abortion, or by an unlicensed midwife or physician for signing birth or death certificates, have been known to appear alluring and as legitimate pot boilers.

Commissions are given to physicians by a consultant for every patient sent to him, or they are given by pharmacists or commercial houses dealing in instruments or surgical supplies—a wide-

spread custom,—or rebates are offered by hospitals and sanatoria to those sending patients. This is called "fee-splitting."

That the practice of fee-splitting is not unknown in this part of the country, although prevalent elsewhere, is attested by the following extract from the report of the Judicial Council of the American Medical Association to the House of Delegates in 1913, after a most careful canvass of the prevalence of fee-splitting throughout the United States by means of impersonal standard circulars with uniform questions, sent broadcast: "In the New England states the practice (fee-splitting) is not prevalent though it exists to a slight degree in them all, being most prevalent in and towards the larger cities of Massachusetts and in that part of Connecticut that is near New York."

When a commercially inclined general practitioner finds that one of his affluent patients—one worth to him several hundred dollars a year—is developing symptoms that call for a surgical operation, the thought enters his head: "If I send my patient to Dr. X he will perform an operation, will receive a large fee, my patient may not need my services again, and if requiring surgical care will go to Dr. X, and not to me; this source of my income will be cut off. Why should not I get a part of the fee for the operation? If it were not for me Dr. X would receive no fee, and he ought to be willing to share. In our town the agent of the brand of automobile I use receives a commission whenever I buy a car, no matter whether the car is purchased of him or directly from the maker; the insurance agent and the real estate man get their commissions in the same way. Why not a commission for the hard working doctor?" If Dr. X is like minded the fee is split, and then other patients follow in the same path.

A form of dishonesty met with too often in the experience of a surgeon to a metropolitan hospital may be classed as fee-splitting. A practitioner tells his patient who needs an operation that he knows Dr. ———, who is on service at ——— hospital, and he will see that the patient is entered on this surgeon's service, paying only a nominal sum for board and nursing. That he, the practitioner, will assist at the operation and make visits when it is over. Then he renders a bill, while the surgeon, who donates his services to the hospital, receives no pay. Of course, the practitioner does not assist and his visits do nothing more than pro-

vide moral comfort. In another case a practitioner arranges with his well-to-do patient for a given operation, undertaking to have it done by a competent man, and arranging all financial matters himself in behalf of his patient. He selects a skilful young surgeon, not having too much practice, and tells him he has a poor patient who can pay only a small fee. After the operation he sends in a bill, perhaps for assisting, perhaps for doing the operation. The fee is ample and he keeps most of it himself.

The young surgeon suffers much at the hands of the old and close-fisted surgeon who gets him to assist and considers the privilege enough compensation without a money honorarium.

Why is fee-splitting unethical? In the first place because it is a secret understanding between the practitioner and the surgeon. Would the patient select a given surgeon if he knew of the understanding? Most assuredly not. In the insurance business, on the other hand, it is known by all that a commission is paid to the agent. Everything is above-board. Such fees, when not paid, are sued for in the courts.

Second, the patient does not receive the best possible treatment, because the really competent surgeons will not split fees. They are able to get fees of sufficient size because of their ability and experience. Therefore the patient is taken to a second- or third-class surgeon, who tries to make up for his lack of skill or experience by adding split fees to his income.

Third, fee-splitting leads to that grave stigma on the profession,—unnecessary operations. A patient, let us suppose, has a small benign tumor. Dr. X says, "Why should not I have the fee for removing it rather than Dr. Y. If Dr. Y gets hold of this patient he will operate, so I will get ahead of him." It is a question only of diagnosis and knowledge of operative technic. The medical judgment which determines whether an operation is necessary or, if it is, which selects the time most favorable for performing it,—a quality that the patient has a right to expect of his medical attendant, is entirely lacking.

The patient of the fee-splitter pays more for his operation, for the fee must satisfy two instead of one, besides getting inferior skill. The effect of fee-splitting on the public is most disastrous because it destroys confidence in the profession. The effect of this manner of acquiring money on the medical practitioner is bound to be morally deteriorating,—to the general

practitioner, because he practises deceit and makes money while sacrificing his patient's best interests; and to the surgeon, because, after the technic of a number of operations has been learned and fees can be obtained for performing these operations, stimulus is lacking to progress in the science and art of surgery.

FOUR IMPORTANT MEDICAL MEETINGS.

DURING the next ten days there will be in session in Boston, Springfield and New York four important medical meetings. The Clinical Congress of Surgeons of North America will hold its sixth annual session in Boston during the week beginning October 25, 1915. The attention of the Boston profession has already been directed to the importance and interest of this congress by editorials in issues of the JOURNAL for September 23 and October 14.

The Fourth Convocation of the American College of Surgeons is announced to take place in Boston on the evening of October 29. The Fellowship Address this year will be given by President Edmund J. James of the University of Illinois, the subject being "The Surgeon's Debt to His Profession." Dr. John Miller Turpin Finney, President of the College, will confer Fellowships upon about four hundred candidates for Fellowship who have been acted upon by the Board of Regents during the past year. The College now lists about 3200 Fellows. On the afternoon of October 29 will occur the annual meeting of the Fellows of the College, the purpose being to elect members of the Board of Governors, and to consider plans for the activity of the College during the coming year. About 1500 Fellows are expected at each of these meetings.

On Friday and Saturday of this week, October 22 and 23, the second New England Tuberculosis Conference is to be held at Springfield, Mass., under the auspices of the National Association for the Study and Prevention of Tuberculosis. A preliminary program of this meeting was printed in the issue of the JOURNAL for September 9. The purposes of this conference are, first, to discuss matters of special interest to the New England States; second, to bring the facilities and aid of the National Association more closely to bear on local problems; and third, to provide a place of meeting and discus-

ion for those who cannot attend the annual meeting of the National Association. An invitation has been extended to all anti-tuberculosis workers coming to this conference to attend also the Massachusetts State Conference of Charities, which is to be held at Pittsfield, Mass., from October 20 to 22 inclusive. At this Conference will be considered the effect upon the family of modern industrialism, the control and care of the mentally defective, correctional institutions, and other similar topics. The complete program of the tuberculosis conference is as follows:—

FIRST SESSION: FRIDAY OCTOBER 22, 2.30 P.M.

HOTEL KIMBALL

METHODS OF ANTI-TUBERCULOSIS WORK.

Educational Methods, by *Prof. Selskar M. Gunn, Boston, Mass.*
Nursing, by *Miss Mary Beard, Boston, Mass.*
Dispensaries, by *Dr. Eugene R. Kelley, State Department of Health, Boston, Mass.*
Institutions, by *Dr. Harry Lee Barnes, Wallum Lake, R.I.*

SECOND SESSION: FRIDAY, OCTOBER 22, 6 P.M.

RED CROSS SEAL SALES METHODS.

A dinner session will be held in the restaurant on the ninth floor of the Forbes & Wallace Department Store, Pynchon Street. Five minute talks will be given on methods of selling Red Cross Seals; the sale of mail, by school children, by personal solicitation, etc., and the publicity needed.

Opportunity will be given for general discussion.

THIRD SESSION: FRIDAY, OCTOBER 22, 8.15 P.M.

FIRST CONGREGATIONAL CHURCH, COURT SQUARE.

INDUSTRY AND TUBERCULOSIS.

The medical examination of employees, by *Dr. Alan J. McLaughlin, State Commissioner of Health, Boston, Mass.*
Employees' relief and aid associations, by *Dr. Charles J. Hatfield, Executive Secretary, National Association for the Study and Prevention of Tuberculosis.*
Insurance against tuberculosis, by *Lee K. Frankel, Ph. D., Metropolitan Life Insurance Company, New York City.*

FOURTH SESSION: SATURDAY, OCTOBER 23,

9.45 A.M.

WESTFIELD SANATORIUM.

PROGRAMS OF ANTI-TUBERCULOSIS WORK.

For cities of 100,000 or over, by *Seymour H. Stone, Boston, Mass.*
For cities of less than 100,000, by *Miss Mary Van Zile, Beverly, Mass.*
For small towns and country communities, by *Miss Clarissa O. Johnson, Dover, Me.*

FIFTH SESSION: SATURDAY, OCTOBER 23,

10.45 A.M.

WESTFIELD SANATORIUM.

THE DIAGNOSIS OF INCIPIENT CASES OF PULMONARY TUBERCULOSIS.

Lecture on "What the general practitioner should know about tuberculosis," by *Dr. Vincent Y. Bowditch, Boston, Mass.*
Clinical demonstration, showing how to detect early tuberculosis, by *Dr. Henry D. Chadwick, of the Westfield Sanatorium; Dr. Estes Nichols, Lebanon, Me., and others.*

The twenty-fifth annual session of the New York and New England Association of Railway Surgeons, celebrating the quarter century anniversary of that organization, is to be held in New York City on Oct. 21 and 22. At the morning session on Oct. 21 there will be presented a series of six papers, after which Dr. W. H. Marey of Buffalo will deliver his presidential address. At the afternoon session on that day there will be a further series of five papers. The second day of the meeting, October 22, will be devoted to clinics given by the New York surgeons at the various hospitals of the city.

RE-EDUCATION OF DEMENTED PATIENTS IN HOSPITALS FOR THE INSANE.

ANY physician who has had any degree of experience in a hospital for the insane, in fact any physician or layman who has visited such a hospital, is discouraged, distressed, depressed, to an extreme degree, by the many rows and groups of idle, not to say irritable and untidy, demented patients who take up so much of the space in some hospitals for the insane and so much of the time of the attendants and nurses. This situation is both distressing and horrible, not to speak more forcefully. That the problem of occupation and exercise for the insane has been receiving greater and greater consideration in the past few years is quite well recognized. It may be stated, too, that occupation among the insane is a practice which has been followed for quite a time. But it also is a fact that this question has not been given the attention and organization everywhere which it deserves. The idea has not been followed out persistently, scientifically or as thoroughly and generally as it might be done. Most of the occupation employed among the patients in the hospitals for the insane, has, up to the present, been confined to convalescent patients or to non-demented patients. To some extent some of the slightly demented patients, of the better sort, have likewise been given occupation in some of the hospitals. But few real, earnest efforts have been made to see what could be done for the truly demented patients who are indeed a great burden on the nurses, doctors and the hospital as a whole. Most of them have been permitted to spend their time as best they knew how or could under the circumstances, and it is not surprising that as a

consequence we find so many untidy, restless, destructive and quarrelsome individuals in the chronic wards of the hospitals for the insane. Human energy must find its outlet, as a useful or useless, if not harmful, level or path of expression. May it not be that much, if not most, of this untidiness, irritability, restlessness, destructiveness, quarrelsomeness, filthiness, profanity and idleness would disappear from the hospitals for the insane, even among the patients suffering from dementing conditions, if adequate means for occupation and exercise were given to as many patients as possible? Our question is answered in the biennial report of the State Psychopathic Institute at Kankakee, Illinois, issued recently, under date of October, 1914. Under the supervision of Dr. S. N. Clark, physician to the Illinois State Psychopathic Institute, an experiment was carried out to demonstrate that it is perfectly possible by sedulous attention and proper stimulation, to make some of the most demented and untidy inhabitants of the chronic wards fairly respectable individuals and easily cared for. Although the attainment of his object required and received a considerable portion of the time of this physician, the success which crowned his efforts was actually remarkable, so much so that it may be said that this physician has found, as a result of his work, a means of improving the lowest types of demented, as well as a field of great value for the employment of other patients who manifested interest in their work as assistants in the exercises given. So much has been accomplished with the lower type of demented patients that we may rightly expect better results with less mentally dilapidated patients.

The experiment is worthy of a brief recital. A squad of patients who had sunk to the lowest levels in the most chronic wards was chosen. All presented a picture of marked affective deterioration. The methods used in the efforts at re-education consisted in care of the person, simple conversational efforts, listening to music, playing ball, marching to music, dancing, calisthenic exercises, tearing rags for carpet making, such simple household duties as polishing floors, making beds, folding clothing and the like, making reed baskets, plain sewing, and weaving colored paper, as is done so frequently in the kindergarten. The physician was aided in his work by the charge nurse of the ward, and later by some of the more intelligent and reliable

patients. The results that were accomplished were obtained without any extra help. This is certainly noteworthy.

The details can be found in the publication mentioned. The results show clearly and unmistakably that markedly demented patients may be considerably improved in all respects: not excepting expression and appearance, if attention and effort be given to personal need and employment. Although these patients can not now be brought to a level of habits of life which may be seriously compared with the normal, yet the need of such work as here reported being put on a larger scale is surely clearly indicated. It is enough to say that these patients feel better and without doubt are more healthy. From the humanitarian as well as the economical standpoint this work should be carried on more extensively. Much unnecessary work for attendants will be done away with, the general upkeep of buildings, furniture and, by means at least, a hygienic environment thus becomes much more simple, and much less laudable work is a result. The following trenchant statement by Dr. Clark forces home the issue in effective fashion: "Since it is possible with the ordinary facilities present in any hospital to improve the condition of patients of advanced age who have sunk so low in the scale of human activities as had those reported here, it seems justifiable to insist that proper attention and surroundings would prevent the occurrence of such degradation." Here is food for thought for all hospitals for the insane. Nothing and everything should be done to do away with the disheartening sights still seen in the chronic wards of the hospitals which harbor those mentally sick persons who have been labelled insane. And prevention is greater, better and more effective than cure. It is just the condition of these demented patients which has cast a gloom, quite contagious, over so many workers in the hospitals for the insane. Measures such as are here mentioned will do much to lift the burden.

BETH ISRAEL HOSPITAL.—It is announced that the Beth Israel Hospital Association of Boston has purchased a site of land in Roxbury for the erection of a Jewish hospital to accommodate twenty patients.

N EIGHTEENTH CENTURY BRITISH SURGEON.

In the proceedings of the section of the history of medicine of the Royal Society of Medicine for May 19, 1915 (Vol. viii) appears an interesting monograph sketch by Mr. G. C. Peachey of Dr. William Bromfield, some time a London surgeon and practitioner, a member of the Royal College of Surgeons of England, and a British representative of the family whose younger branch migrated early to Boston and has left its name and memory in this city. Mr. Peachey's sketch, reviewed editorially in the issue of the *Lancet* for September 4, 1915, presents the character and personality of Bromfield with singular vividness and probable accuracy.

William Bromfield was born in Holborn, London, and was baptized on July 30, 1713. He came of a family of gentry in Southwark, Surrey, one of whom had been created a baronet at the Restoration. William Bromfield's father, one of the younger and poorer members of the family, was a London apothecary and the son of an apothecary.

Of William's early education nothing is known. We find him first apprenticed for the study of surgery to Mr. John Ranby, to whom he later dedicated one of his books. It is reported that he settled early in practice in Holborn and that he was married in 1736. Apparently he had some literary ambitions, for in this year he published an anatomic syllabus in Latin, a work which he subsequently enlarged and republished in 1743. In 1742 he was appointed to the staff of St. George's Hospital, where he became a colleague of the celebrated John Hunter. This appointment was probably obtained through the influence of his preceptor Ranby, who was surgeon to the Prince and Princess of Wales. It is recorded in the hospital archives that Bromfield suggested the use of copper warming pans to warm surgical dressings in cold weather and that he was the first to heat the operating room.

In 1745 Bromfield was appointed to succeed Ranby as surgeon to the Prince and Princess of Wales, and in 1746 he was made first surgeon of the newly established Lock Hospital in Grosvenor Place. Bromfield's career was now assured, and during the ensuing years he seems to have enjoyed a large and lucrative London practice. He also found time to pursue his literary avocations, and in 1755 a play by him, entitled "The Schemers, or The City Match,"

was performed at the Royal Drury Lane Theatre. In 1760 Bromfield was appointed to the court of assistants of the surgeons' company at London, and in 1769 he became master of the company and was appointed to the Queen's household. He now retired from active practice and became consulting surgeon to the Lock Hospital, where he was succeeded on the active staff by his son Charles. Another son, William Heriot Bromfield, was also a surgeon.

Bromfield served as master of the company of surgeons until 1780, when he resigned and received a vote of thanks "for his long benevolent and highly useful assistance." During his later years Bromfield's reputation was somewhat overshadowed by the growing fame of Percival Pott. It does not appear that he was a man of brilliancy, but rather that he succeeded by a combination of energy, moderate ability and court favor. Mr. Peachey in his article says of him: "He was arrogant and self-assertive; and manually efficient though he was, we have been unable to discover in him the possession of either exceptional intellect or extraordinary intelligence."

"He twice sat for his portrait, appearing on one occasion, old, fat, dyspeptic, and grumpy, and on the other—when Cosway painted him according to that artist's flattering convention—elegant, intelligent, and fairly middle-aged. He preferred Cosway's portrait, and in his will left copies of it, handsomely framed, to three of his colleagues."

Bromfield has been credited with various surgical discoveries with regard to the ligature of vessels for aneurysm, to the reduction of a dislocated shoulder joint, to the use of moulded pasteboard splints and to the invention of two lithotomy instruments; but it does not seem that these claims are justifiable.

Besides his friendship with his tutor Ranby and his colleague Hunter, Bromfield was also on intimate terms with Dr. Thomas Lawrence, Samuel Johnson's physician and friend, of whom we published a sketch in the issue of the *JOURNAL* for September 23. Bromfield, however, had the misfortune to survive most of his coevals and his two sons, and in spite of the ill health of his later years lived to the considerable age of eighty, dying in 1792. His was a strongly marked and distinguished character of the medical profession of his time and his personality and the history of his associations and life remain vividly human even after the lapse of two centuries.

MEDICAL NOTES.

PREVENTION OF BLINDNESS FROM WOOD ALCOHOL.—Attention of druggists in New York City has been called forcefully to the provision of law prohibiting the use of methyl alcohol (wood alcohol) in any toilet preparation or medicinal preparation used internally or externally, and to the necessity for the proper labelling of all containers of methyl alcohol. The Department of Health is strictly enforcing this section of the sanitary code.

Some time ago an inspector of the Bureau of Foods and Drugs procured a sample of wood alcohol for rubbing from a drug company in Brooklyn. The alcohol was sold in pint bottles with a label stating the contents to be "alcohol." Analysis showing that the sample was methyl alcohol, prosecution was commenced for violation of the sanitary code. The defendant was convicted in the Court of Special Sessions of Brooklyn on June 3, 1915, and was fined \$250. The justices were so impressed by the health menace occasioned by the human use of wood alcohol that they suggested giving the case the widest possible publicity.

At the last annual meeting of the New York State Pharmaceutical Association the question of the wood alcohol label was discussed and resolutions were adopted requesting the members of the Association and druggists in general to make use of the poison label on wood alcohol which the State Pharmaceutical Association would formulate. The president, Arthur S. Wardell, writes, "This year we shall have about thirty-seven hundred copies of the annual report and one of these copies will go to nearly every druggist in the state of New York whether he is a member of the Association or not, and in this way, those who were not present at the convention will be advised of the action that was taken by the convention in reference to the wood alcohol matter." He further states that the legislative committee of the New York State Pharmaceutical Association was instructed, at its annual meeting, to have a bill introduced in the coming session of the legislature, making the use of the advocated wood alcohol label compulsory.

In connection with wood alcohol poisoning, the following news item, clipped from the *New York Evening Mail*, is of interest:

"Up to April 1, from the date of the suppression of the vodka traffic, there have been treated in the Peter and Paul and Obhovsky hospitals 2,882 victims of methylated spirit drinking. Of these, 27 died.

"In two hospitals for treatment of eye diseases there have been treated 138 patients suffering from partial or total blindness from the same cause. The spirit is obtained by treatment of varnish and eau de cologne. The foregoing is the result of the investigation by a special committee named to report to a military commission."

A NEW DISINFECTANT.—The United States Public Health Service has recently issued the following statement relative to a new and apparently valuable antiseptic:

"As a result of experiments conducted at the hygienic laboratory of the United States Public Health Service it is announced that a new disinfectant, possessing qualities superior to ordinary disinfectants, has recently been discovered. The announcement is particularly important at this time, coming as it does in the face of the shortage in coal tar derivatives which has resulted from the European conflict.

"The new preparation is derived from pine oil, a by-product in the manufacture of turpentine. It is easily prepared by mixing certain proportions of the oil with rosin and sodium hydroxide solution, the finished product being a reddish-brown liquid, rather thick and oily in appearance but free from turbidity. With water it makes a perfectly white emulsion, much resembling milk. It has a pleasing odor, no objectionable taste, and attacks neither fabrics nor metals. It possesses over four times the disinfectant properties of carbolic acid and is altogether nontoxic, so that it may safely be used as a throat spray or mouth wash in solutions of the ordinary strength. The cost of the preparation is remarkably low as it can be manufactured for less than fifty cents a gallon, solely from products which are produced in this country.

"Many of the disinfectants now on the market are neither efficient nor economical, it having been demonstrated that a number of the most expensive and widely advertised are extremely weak in disinfecting power, so much so that their strength is undeterminable by ordinary methods. The sale of compounds of this nature constitutes a fraud. A second class of proprietary preparations are of guaranteed strength, thus putting a legal responsibility upon the manufacturer, but the cost of these per unit of disinfecting power is frequently excessive. The householder is therefore often at a loss to select a disinfectant which is efficient, economical and of constant strength, and it is believed that this new compound, which is to be known as 'Hygienic Laboratory Pine-oil Disinfectant,' will become one of the most useful preparations of that character."

THE INTERSTATE COMMISSION TO FIGHT MOSQUITOES IN 1916.—In order to avoid a repetition of this year's mosquito experience, Commissioner Goldwater proposes the formation of an Interstate Commission to fight mosquitoes in 1916. New York City was not alone in its suffering from mosquitoes during the past summer; the situation was no better in the neighboring States. The residents of the nearby States have a common interest in this matter with those of New York City. Furthermore, no permanent relief from the nuisance can be expected by New York, unless vigorous preventive measures are simultaneously prosecuted in Connecticut, New

Jersey, and Westchester County. For these reasons, the formation of an Interstate Commission is proposed. It will be organized, if Dr. Goldwater's plans are carried out, at the end of this year. The U. S. Public Health Service has been invited to join and has been requested to nominate a chairman to direct the work of the Commission.

PHYSICAL EXAMINATION OF SCHOOL CHILDREN BY PRIVATE PHYSICIANS IN NEW YORK.—The attention of all physicians of the city is called to Section 200 of the Sanitary Code and to the Regulations Governing the Physical Examination of School Children of the City of New York.

It is the desire of the Department, so far as possible, to have all school children physically examined by their private physicians, and to have the medical inspectors assigned to duty in the schools examine only those children whose parents are unable to afford the services of a private physician. In this work, the Department counts on the coöperation of the medical profession. The prompt examination of all children who apply to their own physicians for this purpose, with the immediate return of the card, properly filled out, will greatly facilitate the work of the Bureau of Child Hygiene, which has this matter in charge. Physicians are asked to read carefully the section of the Code, the Regulations and the card form upon which the results of the physical examination and the treatment provided must be indicated. Health certificates not made out in conformity with such regulations and on the card form provided for that purpose cannot be accepted by the school authorities. A copy of the card form together with the Regulations of the Board of Health with respect to these examinations is being sent to all physicians in the city with this number of the bulletin.

DESERVED CREDIT TO A PIONEER.—Although good milk" was distributed to the sick poor of New York as far back as 1873 by the New York Diet Kitchen Association and milk pasteurized and modified to a set formula was dispensed to sick babies in the summer of 1891 by the Good Samaritan Dispensary, the credit for most of the effective pioneer work in the establishment of the present system of infants' milk stations belongs to Mr. Nathan Straus, who in 1892 established his pasteurized milk laboratories with depots in various parts of the city. Our readers may be interested to know that during the year ending September 1, 1915, Mr. Straus maintained eighteen milk stations in Manhattan, eight of them open throughout the winter. At these stations there were supplied 2,175,208 bottles of modified and pasteurized milk and 1,441,530 masses of pasteurized milk. In addition, medical advice was supplied at each station. There is no doubt that this work has been an appreciable factor in the reduction of the infantile death rate in the city.

THE NORTH AMERICAN CHILDREN'S SANITARIUM.—An interesting record of the year's activi-

ties has been published by the North American Children's Sanitarium in Atlantic City. This charitable organization was established in 1910 at Atlantic City for the treatment of surgical cases of tuberculosis by the efforts of the North American. During this time 150 children have been admitted to the hospital of which 114 have been discharged. The report states that it has been the policy of the home to admit children, who, on account of their unhygienic home surroundings, have been unable to successfully combat the disease and to give them the benefit of the maximum amount of sunshine and salt air. In addition, the restoration of function of the diseased part has been attempted by means of rest in bed with extension and fixation by brace and plaster-of-paris cast. To obtain satisfactory results from such treatment it has been found necessary to keep the patients for a much longer period of time than is customary at most seashore sanatoria. The average length of stay at the institution has been 296 days.

The results of this method of treatment have been very gratifying. Of the 150 cases admitted, 108 have improved, 23 have not improved, 1 case ended fatally from tuberculous meningitis, and in 18 cases the results were not recorded.

ROCKEFELLER INSTITUTE FOR THE STUDY OF ANIMAL DISEASES.—It is announced that the buildings of the projected Rockefeller Institute for the study of animal diseases are now under construction on a tract of land near Princeton, N. J., and it is expected that they will be completed within a year. Meantime the director of the institute, Dr. Theobald Smith, and the other members of its staff have begun work in a suite of rooms temporarily lent by the departments of biology and geology of Princeton University.

CLEVELAND MEDICAL LIBRARY.—The will of the late Dr. Dudley P. Allen, formerly professor of surgery in Western Reserve University contains a bequest of \$200,000, as a permanent endowment fund for the Cleveland Medical Library.

PREVALENCE OF MALARIA, MENINGITIS, PELLAGRA, POLIOMYELITIS, SMALLPOX AND TYPHOID FEVER.—The weekly report of the United States Public Health Service for October 1, shows that during the month of August there were in Virginia 2015 cases of malaria, 13 of cerebro-spinal meningitis, 76 of pellagra, 14 of poliomyelitis, 11 of small-pox and 785 of typhoid fever. During the same month there were in Massachusetts 25 cases of malaria, 10 of cerebro-spinal meningitis, 4 of pellagra, 27 of poliomyelitis and 235 of typhoid. There were 48 cases of small-pox in Kansas, 47 in Minnesota, 92 in Illinois and 94 in Indiana. There were 242 cases of typhoid fever in Indiana, 176 in Kansas, 96 in Michigan, 109 in Minnesota and 113 in Washington. It is estimated by the United States Public Health Service that the total number of cases of pellagra in the United States is probably between 25,000 and 100,000.

DECLINE OF BRITISH BIRTH AND MARRIAGE RATES.—In the issue of the *JOURNAL* for Oct 7, we commented editorially on certain aspects of the declining birth-rate in England. The British registrar general has recently issued his return of births and deaths during the second quarter of the current year, presenting further details of this decline and interesting relative statistics of the birth and death rates in different parts of the country.

"The 213,094 births registered in England and Wales last quarter were equal to an annual rate of 22.9 per 1,000 of the population, estimated at 37,302,983 persons. This rate is 3.3 per 1000 below the mean rate in the ten preceding second quarters, and is the lowest rate recorded in the second quarter of any year since civil registration was established. The birth-rates in the several counties last quarter ranged from 16.0 in Sussex, 17.0 in Somerset, 17.1 in Westmorland and 17.3 in Cardigan, to 27.2 in Stafford, 27.3 in Carmarthen, 27.5 in Northumberland, 28.3 in Glamorgan, 28.5 in Monmouth and 30.8 in Durham. The excess of births over deaths last quarter was only 74,515, against 102,293, 105,727 and 101,933 in the second quarters of the three preceding years. The 138,579 deaths registered in England and Wales during the quarter under notice were equal to an annual rate of 14.9 per 1,000, against an average rate of 13.7 per 1,000 in the corresponding quarter of the ten preceding years. The death-rates in the several counties last quarter ranged from 11.2 in Middlesex, 12.0 in Essex and in Rutland, 12.4 in Berkshire, and 12.5 in Buckinghamshire and in Dorset, to 17.2 in Cumberland, 17.3 in Montgomery, 17.7 in Durham, 17.8 in Denbigh, 18.3 in the North Riding of Yorkshire and 18.4 in Cardigan. The 138,579 deaths from all causes last quarter included 311 which were attributed to enteric fever, 6 to smallpox, 6,724 to measles, 590 to scarlet fever, 2,589 to whooping cough, 1,176 to diphtheria and 1,496 to diarrhea and enteritis among children under 2 years of age. The mortality from measles was nearly double the average, and that from diphtheria was slightly above the average; from scarlet fever and whooping cough the mortality was slightly below the average, and that from enteric fever was 40% below. The rate of infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 97 per 1,000, which was 2 per 1,000 above the mean rate in the ten preceding second quarters."

THE CONTROL OF CANCER IN ENGLAND.—The American Society for the Control of Cancer has recently circulated the following statement taken from the weekly press service of the American Medical Association, and advocates its emphasis in medical journals as an example of methods for the control of cancer. This item refers to the public educational movement for

this purpose in Portsmouth, England, and is based on the annual report for 1914 of the local health officer, Dr. A. M. Fraser, which shows that during 1914, there were only 197 deaths from cancer in Portsmouth, as compared with 230 in 1913.

"When the educational measures were put in force two years ago, the cancer death rate of the city had for a long period been increasing. Twenty years ago the average death rate from cancer in Portsmouth was 6.79 per 10,000 of the population, but in 1913 it had risen to 9.16 per 10,000. In that year the total number of deaths was only 34 less than were caused by tuberculosis. While admitting that the increase in the recorded cancer death rate might have been caused in part by improved methods of diagnosis, the Health Committee of the Portsmouth Town Council nevertheless believed that the present number of deaths was unnecessarily large, and they felt it incumbent to adopt whatever measures might lessen the ravages of the disease. The initiative came from Dr. Charles P. Childe, senior surgeon of the Royal Portsmouth Hospital and a member of the Health Committee of the Town Council. As early as 1906 Dr. Childe in his book 'The Control of the Scourge,' had given to the public the benefit of his extended experience with cancer. At his suggestion the Portsmouth authorities in 1913 began a campaign of public education under the official auspices of the Health Department. The methods adopted included the monthly publication in the local newspapers of articles regarding cancer and the printing and distribution of a Health Department circular on the subject. Arrangements were made for periodical lectures to midwives, nurses, and to those engaged in social work in Portsmouth. The Health Department further made provision for free microscopical examinations and reports on suspected cancerous growths in order to assist physicians in immediate diagnosis in the case of patients who were unable to pay for such laboratory service. The experience of the Portsmouth authorities had been that by far the majority of patients who presented themselves at hospitals suffering from cancer exhibited the disease in a stage too advanced to be cured. It was held that the reason for this delay in seeking advice was not as a rule because patients feared operation, but because they were ignorant that they were suffering from anything serious until they began to suffer pain. The fact that cancer at its onset is almost always painless should be widely realized in order that the public may learn the importance of other symptoms which will enable them to recognize the disease in the early stages, when it can nearly always be successfully removed by competent surgery."

EUROPEAN WAR NOTES.

RETURN OF DR. JACKSON.—Report from Naples by way of Paris states that on October 6, Dr. Thomas W. Jackson, chief inspector of the

American Red Cross Sanitary Commission in Serbia, arrived at that city whence he will soon return to the United States.

CHOLERA IN AUSTRIA AND GERMANY.—During the week ended July 26, 1915, there were in Hungary 434 cases of Asiatic cholera with 240 deaths and in Croatia-Slavonia, 320 cases with 157 deaths. In Germany during the week ended August 14, 1915, there were 172 cases of Asiatic cholera with 28 deaths. The majority of these were among prisoners of war.

AMERICAN HOSPITAL AT MUNICH.—In previous issues of the JOURNAL we have, from time to time, noted the work of the American Hospital at Munich which is being conducted under the auspices of the Bavarian Red Cross with funds subscribed by Americans independent of the American Red Cross. At the withdrawal of the American Red Cross units on October 1st, therefore, this hospital was not obliged to be discontinued but will carry on its work as long as sufficient funds can be raised. It has devoted itself particularly to the ophthalmic surgery of Bavarian soldiers who have received eye injuries.

CONTINUANCE OF HARVARD SURGICAL UNIT.—It is announced that a Harvard Surgical unit is to be maintained in service in Europe during the coming winter. Dr. Edward H. Nichols, who organized the previous Harvard unit, has issued the following notice and call for applications.

"Applications are desired from surgeons, physicians, dentists and nurses who are willing to serve with another Harvard surgical unit in a British hospital. Applications must be for a service of at least six months. Transportation will be paid both ways. The pay will be the regular army rates, with additional allowances.

"Preference will be given to Harvard medical men, and men who recently graduated at hospitals. The unit will sail within three weeks. Applications are to be made to H. H. White, University Press, Cambridge, between 9 A. M. and 5 P. M. daily."

It was originally intended that surgical units from Columbia and Johns Hopkins should continue the work of the Harvard unit; but, as these institutions find it not feasible to carry out their plan, the duty will devolve upon Harvard.

AMERICAN SURGICAL UNITS IN RUSSIA.—Report from Petrograd by way of London states that on Oct. 4 there arrived in that city nine American physicians and thirty-eight nurses, constituting the majority of the personnel of the four American Red Cross units which have been in service in Germany and Austria since Dec. 1. These units, which are in charge of Dr. Cary N. Snoddy of Knoxville, Tenn., are acting under the auspices of the American Red Cross, though their expenses are being paid by the German government. They are to take care of the Aus-

trian and German civil and military prisoners in Russia. Their headquarters will be established at Moscow, whence their activities will be distributed among the various detention camps throughout the Russian empire.

RETURN OF DR. STRONG.—Report from New York states that on Oct. 4, Dr. Richard P. Strong arrived in that city aboard the steamer *Duca degli Abruzzi*. He is said to have stated that the total number of deaths from typhus fever in Serbia has been about 140,000. Dr. Strong proceeded from New York to Washington to make a report on his work in Serbia to the Rockefeller Foundation. It is announced from Washington, D. C., that on October 7, Dr. Richard P. Strong presented at the American Red Cross and Rockefeller Foundation headquarters in that city his report of the work of the American Red Cross Sanitary commission in the eradication of typhus fever in Serbia.

"Through the combined efforts of many workers and under the general supervision of the International Health Commission, which was formed at Nish, Serbia, of British, French, Russian, Serbian and American sanitary forces, and of which Dr. Strong was elected medical director in active charge, the epidemic rapidly declined and in the last three weeks before Dr. Strong's departure from Serbia not a fresh case of typhus could be found in the country.

"The sanitary demonstrations in the prevention of typhus which have been given the Serbian people and the construction of the various disinfecting plants throughout the country should prevent the occurrence of another epidemic of typhus. Serbia, however, is still in great need of medical men, and if fighting is resumed she will not have a sufficient number of physicians, surgeons and nurses to care properly for her wounded alone.

"The American Red Cross Sanitary Commission, which was sent to Serbia last spring, was financed by the American Red Cross and the Rockefeller Foundation jointly. The entire country of Serbia was divided into fourteen sanitary districts and an organization was perfected whose machinery ran very smoothly and effectively.

"There was a house-to-house hunt for typhus victims, who were promptly removed to special wards in hospitals; disinfection of victims and those with whom they had come in contact, disinfection of clothing, disinfection of houses, all systematically prosecuted. Rigorous quarantine rules were established and occasionally heroic measures had to be resorted to.

"In some cases, the districts were so badly affected that it was necessary to evacuate them en masse and to destroy, by partly tearing down and by fire the majority of the dwellings.

"As typhus is conveyed from man to man by vermin, the bathing and disinfection of large numbers of people and immediate disinfection of their clothing was an important problem. For

this purpose sanitary trains consisting of three converted railroad cars each were fitted up. One car contained a huge boiler, which supplied the steam for disinfection of the clothing. In a second car fifteen shower baths were constructed. A third car was fitted out into a huge autoclave, into which steam could be turned in two atmosphere pressures. In this manner the vermin were immediately destroyed and the clothes thoroughly disinfected."

Dr. Strong has now returned to his duties as professor of tropical medicine at the Harvard Medical School. On Friday of last week, Oct. 15, a special meeting of welcome in his honor was held in the Faculty Room by professors and distinguished guests of the University.

HONORS FOR AMERICAN PHYSICIANS IN SERBIA.—Crown Prince Alexander of Serbia has bestowed decorations on forty-three American physicians and sanitary engineers in appreciation of their services in checking the typhus epidemic in that country.

EUROPEAN WAR FUNDS.—On October 15, the totals of three of the New England relief funds for the European War reached the following amounts:

French Wounded Fund.....	\$17,941.49
Italian Fund.....	8,872.20
Surgical Dressing Fund.....	3,381.00

BOSTON AND NEW ENGLAND.

APPOINTMENT OF A MEDICAL SCHOOL INSPECTOR.—The appointment of Dr. Laura A. C. Hughes as medical inspector of schools in Boston is announced. Dr. Hughes is to have charge of the nurses in the child hygiene division of the health department at a salary of \$1200 a year. She was formerly a school physician under the previous organization of the department and is now the only woman physician who has been appointed a medical inspector in the present department.

AMERICAN ACADEMY OF DENTAL SCIENCE.—A meeting of the American Academy of Dental Science was held in Boston on October 6. The principal address, on military dentistry, was given by Dr. William H. Potter of Boston who has been on service at the American Hospital in Paris.

HOSPITAL BEQUEST.—The will of the late Julia C. Greenwood of Brookline, Mass., which was filed on October 8, in the registry of probate at Dedham, Mass., contains a bequest of \$3000 to the Vincent Memorial Hospital.

BOSTON MILK AND BABY HYGIENE ASSOCIATION.—The report of the director of the Milk and Baby Hygiene Association shows a considerable increase in the number of babies cared for during the past summer with a commendable decrease in number of deaths. The figures are:

Number of babies cared for in the summer of 1913, 2185, in 1914, 2556 and in 1915, 2997.

The number of nurses' visits to the homes of registered babies in 1912 was 10,115; in 1913, 13,644; in 1914, 17,206; and this year, 16,666. The number of deaths among babies registered with the association was 29 in 1912; 16 in 1913, 15 in 1914, and six in 1915. The increase in the weekly clinics held for well babies has nearly doubled in two years.

PROPHYLACTIC ANTI-TYPHOID INOCULATION AT HARVARD.—It is announced that Dr. Roger I. Lee, professor of Hygiene at Harvard College, has planned to provide optional prophylactic anti-typhoid inoculation for all members of the University. This was also done last spring when 175 men were treated and it is hoped that a much larger number will volunteer for the inoculation this fall.

DARTMOUTH MEDICAL ALUMNI ASSOCIATION.—On October 8, a joint meeting of the Dartmouth Medical Association and the New Hampshire Surgical Club was held in Hanover, N. H. The presidential address of the former organization was delivered by Dr. C. H. Carleton of Hanover, and other papers were read by Dr. W. J. Mixer of Boston and Dr. H. L. Smith of Nashua, N. H.

The Dartmouth alumni elected these officers: President, Dr. E. H. Carleton, '97, of Hanover; first vice-president, Dr. E. A. Beaton, '98, of Franklin; second vice-president, Dr. W. A. Bartlett, '11, of Manchester; secretary-treasurer, Dr. H. N. Kingsford of Hanover; executive committee, Dr. C. F. Flanders, '81, of Manchester; Dr. E. P. Lord, '03, of Hanover, and Dr. A. R. Kington of Boston.

The New Hampshire Surgical Club elected Dr. W. H. Lyons of Manchester, president; Dr. G. C. Wilkins of Manchester, vice-president, and Dr. C. E. Congdon of Nashua, secretary-treasurer.

QUARANTINE FOR FOOT AND MOUTH DISEASE.—As a result of the reeruption of the foot and mouth disease in Illinois, which we noted in last week's issue of the JOURNAL, the Massachusetts Bureau of Animal Industry has issued the following orders closing the stockyards at Brighton and Watertown in this state, and declaring an embargo against cattle, other ruminants and swine from Illinois.

"Section 1. The bringing of cattle, sheep, other ruminants and swine into the Commonwealth of Massachusetts from the State of Illinois for any purpose whatever is hereby prohibited, except on written permission of the commissioner of animal industry.

"This order shall not apply to animals in transit from some other State through the State of Illinois, provided the same are intended for immediate slaughter, and consigned to slaughtering establishments under federal inspection, and provided further that the animals are not unloaded in said State from the cars or vehicles in which they were originally shipped.

"Section 2. This order shall be published by sending copies to railroad companies engaged in the transportation of animals to Massachusetts and to persons, firms, or corporations which receive interstate shipments of animals intended for slaughter."

The order closing the stock yards reads as follows:—

"Owing to the receipt this day at the premises of the Brighton Stock Yards Company in Brighton, within the city of Boston, Mass., of an animal suspected of being affected with foot and mouth disease, said premises and all meat cattle, sheep, other ruminants and swine now contained in the barns and yards of said premises are hereby placed in special quarantine until released therefrom by the commissioner of animal industry.

"During the existence of this special quarantine, all persons entering or leaving said premises shall be subject to such regulations as the commissioner of animal industry may deem necessary in order properly to enforce and maintain said special quarantine.

"The Union Market Stock Yards at Watertown are hereby declared closed until further notice."

On Oct. 11 it was reported that a recurrence of the epizootic had been discovered among seven cows in a herd at Leicester, and accordingly the whole of Worcester County was placed under provisional quarantine.

An active protest has been made by cattle owners against the hardship and pecuniary loss to them involved in these regulations.

MEETING OF SOCIAL HYGIENE ORGANIZATIONS.

—In the issue of the JOURNAL for Sept. 30 we published the preliminary program of the meeting of the American Social Hygiene Association in conjunction with the Massachusetts Society for Social Hygiene. This meeting was held in Boston on Oct. 8, and was attended by about 150 members. The afternoon session was devoted to a symposium on the problem of venereal disease and addresses were made by Dr. Donald R. Hooker of Baltimore, Dr. Edward L. Keyes, Jr., of New York; Dr. Allan J. McLaughlin, Massachusetts State Commissioner of Health; Dr. George H. Kirby of New York, Dr. Gardner T. Swarts of Providence and Dr. George W. Goler of Rochester. The evening session was a public meeting, at which there were addresses by Dr. Henry P. Wolecott, Dr. Charles W. Eliot and others.

At the business meeting of the American Social Hygiene Association, which occupied the forenoon session, the following officers were elected for the ensuing year:—

Abram W. Harris, president of Northwestern University, president; Dr. Charles W. Eliot, honorary president; active vice-presidents, David Starr Jordan, William T. Foster, Felix M. Warburg, Walter T. Sumner; treasurer, Henry L. Higginson, Boston; secretary, Donald R.

Hooker, M.D., Baltimore; directors, Thomas M. Balliet of New York, Mrs. C. A. Herter of New York, Mrs. Martha P. Falconer of Darlington, Pa.; William A. Greer of New York, Deleavere King of Boston, Dr. Lawrence Litchfield of Pittsburgh, James B. Reynolds of New York, and E. R. A. Seligman of New York.

Dr. William F. Snow, the general secretary, presented his annual report, which showed that the membership had grown during the year from 172 to 470, representing 33 states, of which California has 17 members, Connecticut 14, District of Columbia 10, Illinois 27, Maryland 22, Massachusetts 92, New Jersey 23, New York 148, Ohio 17 and Pennsylvania 35, the other states having smaller representations. It is estimated that by the work the organization has done this year it has reached directly about 150,000 individuals.

As counsel for the association James B. Reynolds of New York read a report which dealt exhaustively with the subject of investigation and legislation. He stated that 28 Legislatures had measures before them last year dealing with the question of social diseases. There were about 500 measures which reached the association and were reviewed by it and summarized and returned to the legislative bodies with suggestions. Nearly all the states passed some legislation bearing upon the subjects in which the association is interested.

Obituary.

PROFESSOR PAUL EHRLICH.

DR. PAUL EHRLICH, who died on August 20, at Bad Homburg, Germany, was born of Jewish parentage on March 14, 1854, in Strehlen, a small Silesian town some twenty miles south of Breslau. He received his preliminary schooling at Strehlen and entered the University of Breslau at an early age. His family had produced several scientists of distinction, notably Dr. Karl Weigert, the celebrated pathologist, who was Paul Ehrlich's cousin. Ehrlich himself is said to have been but an indifferent student at the gymnasium and the university, preferring to devote his time to original experimentation rather than to the routine of academic work. He was recognized, however, as a man of unusual talent and finally graduated from Breslau with distinction. Later he obtained the degree of M.D. from the University of Strassburg, and subsequently continued his medical studies at Freiburg and at Leipzig. In 1877 he qualified as a medical practitioner in Breslau, and in 1878 he was appointed chief assistant in Frerich's medical clinic at Berlin, where he remained for seven years.

Ehrlich's genius, however, was for laboratory investigation, not for clinical practice. In 1884 he was made a titular professor by the Prussian government and in 1887 became a docent at the

University of Berlin. In 1888 the impairment of his health, leading to a suspicion of phthisis, compelled him to abandon his work and to travel for a year and a half in Egypt and other countries. Returning to Berlin in 1890 he was given a place in the laboratory of Dr. Robert Koch and received the title of professor extraordinary at the University of Berlin.

Ehrlich now undertook the experimental study of toxins and anti-toxins, in the course of which he began the extensive researches in serology and cellular pathology which first attracted the attention of the scientific world. In 1896 he was made director of the Royal Institute for Serum Research at Steglitz near Berlin. In 1897 he was made a privy councillor by the Prussian government, and in 1899 director of the Royal Institute for experimental therapeutics at Frankfurt-on-Main. Here he undertook, with Morgenroth, the study of hemolysis. In 1900 he was selected to deliver the Croonian Lectures at London. In 1902 he followed Jensen of Copenhagen in an investigation of malignant tumors of mice, and for his work on immunity received, in 1903, the gold medal for science from the King of Prussia. In 1904 he published his collected studies in immunity, and was made an honorary professor in that subject at the University of Göttingen. It was in this year also that he visited the United States, lectured in several of our larger cities and received the honorary degree of LL.D. from the University of Chicago.

In 1906 the Institute for Chemical Therapeutics was established at Frankfurt by Mrs. George Speyer and Ehrlich was made its director. Here he devoted himself to the science of chemotherapy, of which he must be considered the essential originator, and began his series of researches in sleeping sickness and syphilis, which resolved itself into a study of the synthetic organic compounds of arsenic, and culminated in the discovery of salvarsan and neo-salvarsan. In 1907 he was made chief medical privy councillor of the Prussian government, delivered the Harben lecture in London and received the honorary degree of Sc.D. from the University of Oxford. In 1908 he divided with Metchnikoff the Nobel prize of that year for work in immunity. In 1913 he delivered the oration in pathology before the International Medical Congress in London. In 1914 he was awarded the Cameron prize of the University of Edinburgh and received from Emperor William the second class of the Order of the Red Eagle.

Dr. Ehrlich was a man of incessant and brilliant mental activity, capable of intense concentration, and a prolific author. Between 1877 and 1914 he contributed 212 books and papers to the literature of science. His first important work, on the oxygen requirement of the organism, was published in 1885. In it he recorded his early use of the various aniline dyes and presented the first outline of his famous side-chain theory.

Ehrlich's life has been divided into four periods: the first, from 1877 to 1890, was devoted to chemical studies and to experiments with aniline dyes; the second, from 1890 to 1899, to the study of toxins, anti-toxins, the chemistry of immunity, and to the development of the side-chain theory. The third, from 1899 to 1906, to the study of hemolysins, of malignant disease in rats and mice, and to the completion of the side-chain theory by the theory of amboceptors; and the fourth, from 1906 to 1915, to the study of chemotherapy, especially in the treatment of trypanosomiasis. In its description of his life, in its issue of August 28, the *Lancet* presents in part the following account and analysis of his scientific work:—

"Paul Ehrlich will be remembered for his investigations on the specific action of dyes on living tissues, for the 'side-chain' theory, and for the discovery of salvarsan. Possessed of the truly scientific spirit in the highest degree, his aims were yet consistently practical and utilitarian, and even his speculative and highly involved hypotheses had a practical aspect, and were often used simply as a scaffolding upon which to build further advances in experimental work. It is this aspect of his energies which has served to secure for him a world-wide acknowledgment and recognition during his lifetime such as few scientific men achieve. This practical bias of mind puts Ehrlich in company with Pasteur, Lister, and Koch, whose work he continued and amplified, and perhaps the greatest praise that can be given him is to associate him with them as a worthy compeer. It was in the study of hematology that he first came to the front, and here he was a pioneer. By his careful study of the effects of dyes on various constituents of the blood cells, both red and white, he not only put the study of blood diseases on a scientific basis, but also did perhaps more than any other biologist to elevate the importance of the investigation of cellular reactions and to promote careful research into what has now been raised to the dignity of a special branch of biology under the name of cytology. Here comparatively early in Ehrlich's scientific career we may observe the utilitarian tendency of his work, for the whole structure of modern hematology and all methods for the cytological investigation of exudates, now so valuable in diagnosis, are the direct outcome of his original studies. The use of methylene blue injected *intra vitam* as a means of studying oxidation processes in the body, although a commonplace of the textbooks of physiology, is perhaps less generally known but is none the less a striking original piece of work.

"Another of Ehrlich's practical contributions to the study of immunity, and an important one, was his brilliant work upon the standardization of diphtheria antitoxin. It is always difficult to apply mathematical considerations to complex biological problems, but it was obvious that if antitoxin therapy were to be safe and uni-

rm, this must be done. Ehrlich's solution of is question was a masterpiece of exact investigation, and remains the only practical method of antitoxin measurement and dosage.

"The discovery which brought Ehrlich's name before the public was the introduction of salvarsan. It was no haphazard discovery, but was based on a long series of investigations proceeding along well-defined lines. A necessary corollary of the side-chain theory was the idea that a living cell, be it a cell of the body itself or of an invading microbe, was susceptible to certain chemical combinations, and, therefore, it were to be affected by any drug, that drug must possess certain chemical attributes or no effect would be produced. Hence it follows that definite chemical groups in the drug employed will have definite chemical actions, so that, were our knowledge sufficiently wide, we should be able to predict the action of any drug before it is employed; and although our learning at present falls far short of this extent, yet we can gauge much of the action of an untried chemical substance if its constitution is known. From this basis Ehrlich started on an investigation of a cure for syphilis. He aimed at some substance which should destroy completely all the spirochetæ pallidæ in the body. He started from the fact that arsenic had been used with success in the treatment of syphilis, and he designed to obtain a substance which, while causing the minimum of harm to the human body, would be a potent agent in destroying the spirochetæ. He gave directions to those chemists who assisted him to prepare chemical substances, thus reversing the usual process, where the chemist invents chemical substances which he offers to the physician for trial. Here the physician gave the direction to the chemical investigator. After a large amount of work Ehrlich, at length, evolved salvarsan, or dioxydiaminoarsenobenzol, '606,' as it was called in the convenient phraseology of the laboratory, and the drug was found at once to exert a wonderful influence on syphilis. Experience has confirmed the value of Ehrlich's work. The drug causes a marvellous improvement to occur with extreme rapidity, and though experience has shown that there is no 'sterilisatio magna,' yet the benefit is great and lasting, and this in the vast majority of cases without any harmful effect on the patient. It is true that a number of deaths, in fact many deaths, have followed the use of salvarsan, but in most cases these are explicable by some error in administration or some idiosyncrasy; and it is noteworthy that in several long series of cases there have been no deaths. With the results that have been obtained with salvarsan Ehrlich was not content; he continued his researches, and one result of these is neosalvarsan, which in some respects is an improvement on its predecessor. But Ehrlich, with the spirit of the true philosopher, continued looking for some substance which should be capable of producing

a 'sterilisatio magna,' and the work which he has not lived to accomplish remains to be carried out by others. Although differences of opinion exist as to the ultimate value of salvarsan, there can be no doubt that the medical profession has had put into its hands a weapon of extraordinary power."

The death of Dr. Ehrlich removes one of the most brilliant figures which the scientific world has known during the past half century. Of his personality little is known well except by those who shared in the intimacies of his professional work. He is described as a man intensely pre-occupied, absent-minded of all concerns in life other than the problem on which he was engaged. His death, at a time when his intellectual activities were at their highest and when he might have been expected to carry his researches to still higher achievements, is an incalculable loss to science. Dr. Ehrlich is survived by his widow and by two daughters.

Perhaps the most appreciative and illuminating sketch of Ehrlich's character and of the significance of his discoveries is that contributed to the *British Medical Journal* by Dr. C. H. Browning, director of the Bland-Sutton Institute of Pathology in the Middlesex Hospital.

"It is seldom given to one man by his discoveries to revolutionize the outlook on five or six different departments of knowledge and to open up as many unknown paths along which multitudes of others may make rich journeys of discovery. Thus, his investigations on the staining of the leucocytes laid the foundation of modern hematology; his observation that methylene blue possesses an elective affinity for nerve endings has been the starting point of a whole school of highly fruitful neurological research; it was Ehrlich who discovered the acid-fast property of the tubercle bacillus and who devised the method of staining this organism which is practically that now in every-day use, and without which, as Koch himself admitted, the demonstration of the organism would have remained an academic accomplishment instead of becoming one of the most valuable diagnostic procedures in medicine. Similarly, by his work on the standardizing of diphtheria antitoxin Ehrlich placed the dosage of antiserum on a scientific basis, without which von Behring's great discovery would probably have failed in its wonderful achievement. It is well to recall the earlier work of Ehrlich, because it shows the extraordinary versatility of his mind and the remarkably long period during which he continued to produce results of first-class importance; thus the discovery of the acid-fast character of the tubercle bacillus was published when he was 29 years of age, and the 'Oxygen Requirements of the Organism,' which contained the germ of his chemotherapy, when he was 31, and before he had attracted the multitude of workers who latterly sought his laboratories. In his later days, when he was the director of the busy Institute of Experimental

Therapy and the Speyer-Haus at Frankfurt, with their numerous assistants, it was occasionally forgotten what the man achieved by himself. Of course, it was true that individual workers unearthed treasures, whose existence Ehrlich had not suspected, or of whose sterling value he had occasionally to be convinced, but all who were capable of taking an honest and a generous view, knew well that even if Ehrlich did not always foresee the actual nature of the treasure, it was almost invariably he who had discovered the trove.

"The writer worked at Frankfurt during the period (1905-7) which immediately preceded the discovery of salvarsan, and being engaged on the biological investigation of a large series of the arsenical preparations which preceded the famous '606,' it was his great privilege to be intimately associated with Ehrlich in those themes which were then of all-absorbing interest to him. Ehrlich was in those days, even as earlier, an indefatigable worker, and his mind was the sharp sword which ever tended to wear through the scabbard. Had it not been for the solicitous care of his wife there is little doubt that we should have had to regret his loss still earlier. His knowledge of chemistry, especially in its bearings on biology, was immense; at the same time he possessed a power of concentration which appeared almost uncanny, and which in its capacity for eliminating trifles would quite unfit the average man for the ordinary affairs of life. Ehrlich's writings exhibit a singular felicity of expression; he had a genius for the creation of descriptive phrases, such as his famous *Corpora non agunt nisi frata*, and this same quality made personal association with him a never-failing inspiration and stimulation to fresh effort. He was extremely fond of expressing his ideas symbolically, and the diagrams illustrating his theories on immunity are an example of this; these have probably been taken much too literally, and have produced crude conceptions of the nature of the highly complex class of bodies to which toxins and antitoxins belong, which Ehrlich himself never entertained. Latterly the theories of immunity did not actively interest him, although he was at all times ready to uphold the accuracy of the enormous mass of experimental data on which they were based. It is significant that he did not regard cancer investigation with a very sanguine outlook. Were I to attempt to characterize in brief the genius of Ehrlich, I should say that it consisted in two striking characteristics—his faculty for escaping the trammels of error in past work, and his capacity for bringing into association as the basis for experiments ideas which purely critical minds would tend to dismiss as fantastic. Having effected a synthesis, he was then pre-eminently able to grasp the essential elements. Ehrlich's power to evade the pitfalls of old error was clearly seen in his researches, which led to the elucidation of the constitution of atoxyl; a

belief in the accepted view of its composition as an aniline would have effectually prevented all the further developments which culminated in salvarsan. His synthetic faculty is exhibited by the numerous reactions in pure chemistry with which his name is associated, and his keen gift for analysis is exemplified by his fundamental discoveries on the relationship subsisting between chemical constitution and biological action. This is a time at which it is difficult to see clearly, but one feels sure that the perspective lent by the future will bring into still greater prominence the influence of Paul Ehrlich on the advancement of medicine. It is singular that this man, whose practical contributions to medicine have been so numerous, probably never approached any problem in a utilitarian spirit—pure sciences frequently stand in need of apologists, and Ehrlich's whole career is a striking vindication of the pursuit of knowledge for its own sake. He who seeks finds, and Ehrlich was an inspired seeker."

Massachusetts Medical Society.

STATED MEETING OF THE COUNCIL.

A stated meeting of the Council was held in John Ware Hall, Boston Medical Library, Wednesday, October 6, 1915, at twelve o'clock, noon. The president, Dr. Charles F. Withington, was in the chair and the following 83 councilors present:—

COUNCILORS PRESENT.

BAENSTABLE.	HAMPSHIRE.

WORCESTER,
F. H. Baker.
W. P. Bowers.
C. A. Church.
Homer Gage.
David Harrower.
W. L. Johnson.
G. O. Ward.
L. F. Woodward.
S. B. Woodward.

WORCESTER NORTH,
A. P. Mason.

Hampar Paul Kazanlian, of Lawrence.
Isaac Klein, of Boston.
Wilfrid Teller La Fortune, of Fitchburg.
Samuel Sanford Orr, of Weston.
Sumpt Keyvor Pachanian, formerly of Lowell, present address unknown.
Charles John Peirce, of Shirley Village.
George Merrill Randall, of Lowell.
Frederick Rodney Sanborn, of New York.
Joseph Shohan, of Roxbury.
Henry Marr Stoddley, of Somerville.
Wellington Andrew Thompson, of Manchester, N. H.
Frank Elmer Tilden, of North Easton.
Raymond Sargent Wilder, of New York.

For the Committee on Membership and Finance,

CHARLES M. GREEN, *Chairman*.

A petition of J. J. Sullivan, of Lawrence, for restoration to the privileges of fellowship was referred to this committee: W. H. Merrill, J. A. Dorgan, F. A. Conlon.

A similar petition from O. M. Deems, of Springfield, was referred to J. M. Birnie, E. L. Davis, T. S. Bacon.

On motion by W. C. Howe it was,

Voted: That because of the disturbed state of Mexico Dr. A. W. Parsons, of Tampico, did not receive the notice that the Council had voted February 3, 1915, to restore him to the privileges of fellowship provided he paid past and current dues within two months of the date of the Council meeting, and because he now expresses a desire to be restored under the same conditions it is voted that the time during which he may pay up be extended to December 31, 1915.

Voted: That Dr. A. J. Stevens, of Malden, a retired Fellow, be restored to active fellowship upon his own request, under the terms of Chapter I, Section 5, of the by-laws.

The reports of the committees appointed to consider the petitions of the following for restoration to the privileges of fellowship, namely that they be restored provided they pay past and present indebtedness within one month, were accepted: A. V. Lyon, F. H. Lally, Ada H. Tedford, S. H. Rubin.

Dr. Charles M. Green, Chairman of the Committee on Membership and Finance, introduced this amendment to the by-laws and moved its adoption:

Chapter VII, Section 3, that the word "June" in the last line of the fourth paragraph be changed to "March"; so that the clause shall read: "This dividend shall be apportioned among the district societies according to the number of annual assessments which shall have been paid to the district treasurers previous to March first."

It was discussed by the following councilors: C. M. Green, E. M. Buckingham, G. O. Ward, W. H. VanAllen, A. Worcester, S. B. Woodward, C. W. Milliken and G. W. Kaan. The last named offered an amendment to Dr. Green's motion to the effect that it be indefinitely postponed. On being put to a vote, Dr. Kaan's amendment was lost and the original motion was passed. The appended report of the delegation to the House

The records of the last meeting were read and accepted. The president nominated and the Council appointed these delegates: To the annual meeting of the Vermont State Medical Society in Burlington, October 14 and 15, 1915: Dr. John S. Hitchcock, of Northampton; Dr. Francis P. Emerson, of Boston. In the same manner Dr. E. O. Otis and Dr. W. H. Robey, Jr., were appointed a committee to audit the treasurer's accounts.

The Committee on Membership and Finance presented this report through Dr. Green, and it was accepted and its recommendations adopted by vote:

REPORT OF THE COMMITTEE ON MEMBERSHIP AND FINANCE.

THE COMMITTEE ON MEMBERSHIP AND FINANCE makes the following recommendations as to membership:

1. That the following named Fellows be allowed to retire, under the provisions of Chapter I, Section 5, of the by-laws:

John Standish Foster Bush, of Winchendon.
William Barker Hills, of Brookline.

2. That the following named Fellows be allowed to resign, under the provisions of Chapter I, Section 7, of the by-laws:

William Henry Beardsley, of Springfield.
John Paine Torrey, formerly of Andover, now of Norman, Oklahoma, (to take effect January 1, 1916.)
Earl Morey Vrooman, of North Adams.

3. That the following named Fellows be deprived of the privileges of Fellowship for non-payment of dues, under the provisions of Chapter I, Section 8, of the by-laws:

William Wallace Broga, of Springfield.
Thomas Joseph Cahill, of Cambridge.
Thomas Greene Clarke, of Langley, Washington.
Daniel Hiram Craig, of unknown address.
Herbert Clair Deans, of Roxbury.
Francis William Donahue, of Greenfield.
Edward Hugh Ferguson, of Wrentham.
Charles Lawrence Furenlow, of Springfield.
Edward Richard Gookin, of Dorchester.
Gottfried Leonhard Hagen-Bürger, of Havana, Cuba.

of Delegates of the American Medical Association, last June, was read by the secretary in the absence of Dr. Hugh Cabot:

REPORT OF THE MASSACHUSETTS DELEGATION TO THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION, JUNE, 1915.

Gentlemen:

The most striking feature of the report of the Trustees was the evidence submitted of the profound effect the propaganda against patent medicines was having on the proprietors of these remedies. A formidable list of law suits filed against the Association was presented, but interestingly enough none of them have come to trial and some have already been dropped from the docket. In short, the Association has successfully called these bluffs.

The Judicial Council made a most exhaustive report of the development of Workmen's Compensation laws in this country and abroad, which may be regarded as the most valuable survey of this development hitherto compiled and will prove a most satisfactory document for reference.

This Council also showed its courage by recommending that a certain Fellow against whom charges of advertising had been proved, be dropped from the rolls. This advice was adopted and may be regarded as a good beginning in the enforcement of discipline by this powerful body.

The recommendations of the Council that the Secretary of the American Medical Association prefer charges against any Fellow when overt acts on the part of such Fellow, supported by reasonable proof, were brought to the attention of the Secretary. This will provide a method of preferring charges which will not involve the necessity of having charges brought by another Fellow who might often be unwilling to do so.

The report of the Council of Medical Education showed that it has continued its most remarkable work in aiding the consolidation of medical colleges and raising their standards. It has made a study of hospitals, both from the point of view of clinical teaching and as concerns their availability in providing internships for medical graduates. From this study as a basis we may expect to see this Council use its great influence toward making a hospital year a requirement for practice.

The Council on Health and Public Instruction, acting with the American Bar Association and the American Institute of Criminal Law and Criminology, has prepared a bill for submission to state legislatures regulating expert testimony in criminal cases involving questions of insanity. The bill was made to cover only this small portion of the question of expert testimony in order not to make the experiment too radical and to increase the chance of its adoption and trial. This we believe to be the beginning of a valuable reform.

The general impression left upon one's mind by this year's Session of the House of Delegates was that the Councils have proven a most valuable means of doing an enormous amount of important work and that the House had learned to rely upon them.

It is with pleasure that we record that in spite of the great distance and the amount of time involved in attending the meeting, four out of the five delegates from the Society were in constant attendance.

Respectfully submitted,

HUGH CABOT.

Voted: To accept the report.

Dr. C. J. Allen presented the minority report and Dr. G. W. Gay the majority report of the committee appointed last June to consider the advisability of employing legal counsel in medical matters before the Legislature. After dis-

cussion, participated in by Dr. Allen, Dr. Gay, Dr. Thompson and Dr. Cook, the majority report was accepted by vote.

MAJORITY REPORT.

EMPLOYMENT OF LEGAL COUNSEL.

Gentlemen:

At the last meeting of the Council on June 8, 1915, a special committee was appointed by the president for the following purpose: "To investigate the advisability of employing legal aid in safeguarding the interests of the Society in matters that may come before the Massachusetts Legislature. They shall ascertain the approximate cost of such aid and report with recommendations to the next meeting of the Council."

This committee held a meeting on June 28th, and after a free and harmonious discussion, it was agreed that a majority and minority report should be presented to the Council. The majority report is hereby offered for your consideration.

In the remarks of the chairman of this committee made on presenting the subject to the Council, several reasons were given therefor among which were the following:

First. A report that the National Association of Retail Druggists proposed to make an effort to secure legislation prohibiting the dispensing of medicines by the physicians, except they be legalized druggists. In other words, our patients were to receive no medicines except at the hands of the apothecaries.

A moment's consideration would seem sufficient to convince anyone of the futility of seeking such legislation before a Massachusetts legislature. The most obtuse legislator would at once see not only the absurdity of such a law, but also the impossibility of enforcing it were it placed upon the statute books. This proposition does not seem of sufficient importance to justify any extra expense to the Society.

Second. It was also stated that this Association will seek measures to prohibit the manufacture of all "galenic preparations," by the large manufacturers, and to destroy the trade in nostrums.

The natural inference to be drawn from the instructions submitted to this committee is that the work of the Standing Committee on State and National Legislation of this society is not satisfactory to a portion of its Fellows. A brief examination of the annual reports of that committee for the past ten years, which are in the hands of every member, would seem sufficient to convince reasonable persons that the committee's efforts had been very efficient. Composed of the president and four other Fellows, it has the valuable assistance of an advisory committee of one or more physicians in each of the forty Senatorial Districts of the state. Efforts are made to get in touch with members of the legislature through their family physician and in every other proper way for the purpose of informing them of our objects, the reasons therefor, and of the benefits to the public that we seek to obtain. Furthermore, they are given to understand that the Massachusetts Medical Society has no axes to grind, that it asks nothing of the legislature for itself, but that its sole object is in the welfare of the Commonwealth.

Many years ago, certain members of this Society, who were interested in legislative matters, were told by the public health committee in the Legislature, that it was not necessary to employ counsel for the presentation of medical bills to that committee, as the committee had sufficient confidence in the medical profession to justify their belief that it would not present or advocate unworthy, or improper measures before legislative committees.

For many years the policy of the Committee on State and National Legislation had been founded upon that advice. The committee has the authority to employ counsel upon all proper occasions, and it has availed

self of this privilege in numerous instances. The results of this policy are matters of record and are in the hands of the members of the Society.

The estimated cost of employing counsel, as specified in the vote in hand, has received due consideration. Several first-class attorneys have been consulted upon that point. The estimates have varied from \$500 to \$1500 annually. One thousand dollars would probably be sufficient to secure satisfactory service annually.

The undersigned fail to see any advantage to be gained by employing further legal aid in legislative work than is already the custom upon the necessary occasions. We do not believe that the legislative work in the interests of this Society, nor that the professional work in the interests of the public can be done so well by lawyers as by physicians. From an intimate knowledge of the work and achievements of our Committee on State and National Legislation extending over many years, we believe that the above interests are safer in the hands of this committee and will be managed more successfully by it than can be reasonably expected of any legal body and at much less expense.

For these and other reasons that need not be specified upon this occasion, we recommend that no counsel be engaged or employed to look after legislative matters pertaining to this Society, other than is now the custom of the committee to whose hands they are committed.

Respectfully submitted,
GEORGE W. GAY,
CHARLES M. GREEN.

MINORITY REPORT.
EMPLOYMENT OF LEGAL COUNSEL.

gentlemen:
I regret very much that I am compelled to differ from my colleagues, but believing as I do, that the same has come when the interests of the Massachusetts Medical Society demand the aid of competent legislative counsel, the only course open for me to pursue, is to submit this minority report.

Every year, our profession is made the target of various kinds of attack by various kinds of people, and if we can believe the statements of our friends be enemy, the coming legislative year will witness a series of attacks more vicious than any that have preceded them.

In addition to the usual attempt to break down our legislation laws and weaken our medical registration, it is planned to introduce a bill, the object of which is to prevent physicians from doing any discharging. Back of this bill will be the best organized body of men in this country, possessed of unlimited money with which to hire the shrewdest legal talent available.

I believe that we should place at the disposal of our legislative committee the services of a lawyer, familiar with the wiles of unscrupulous law-breakers, one who is able to meet them at every turn and beat their every game.

I do not believe that it will be necessary or wise for him to make himself prominent at legislative hearings. His work would rather consist in mapping out plans, preparing cases, deciding on available evidence, etc. It is a familiar saying that a case well-prepared is half won.

Such aid can be secured next year for \$1000. This sum can be obtained in three ways: First, let each man who eats it pay for his annual dinner; Second, let the money that is now returned to the District Societies as rebates; Third, let every man pay for his own JOURNAL.

I therefore recommend that \$1000 be appropriated to secure legal counsel, the same to be expended by and at the discretion of, our Committee on State and National Legislation.

Respectfully submitted,
CLARENCE J. ALLEN.

The president referred to the death of Dr. James Edwin Cleaves of Medford, which occurred June 20, 1915, shortly after the Council meeting, which he attended. Dr. Cleaves was sixty-one years old and had been a counselor for many years.

Dr. C. M. Green offered the following motion for the Committee on Membership and Finance, and it was so voted: That the Librarian be instructed, until otherwise ordered, to furnish the business manager of the BOSTON MEDICAL AND SURGICAL JOURNAL by December first of each year, with the number of members of the Society entitled to receive the JOURNAL on March first of that year, and that that number be considered the minimum number of JOURNALS to be paid for by the Society in each respective year.

He stated that the chairman of the Committee on Membership and Finance was instructed to inform the Council that the committee is prepared to recommend the necessary appropriation to continue the affiliation with the BOSTON MEDICAL AND SURGICAL JOURNAL.

Dr. G. W. Gay read a report on Malpractice Defence for the seven years the act had been in operation:

THE FIRST SEVEN YEARS OF MALPRACTICE DEFENCE.
Report Prepared by the Secretary.

As you know, the Malpractice Act of the Massachusetts Medical Society went into effect following the annual meeting of the Society in June, 1908. By the terms of the act any active Fellow whose dues are paid up has the privileges of defence in a suit for damages for malpractice provided the claim is for services rendered subsequent to the adoption of the act, and provided the suit is entrusted solely to the Society to defend. No damages are paid, should the suit go against the Fellow, and a suit may be settled by the defendant only on the consent of the Society.

During the seven years in which the act has been operative, the secretary has discussed malpractice defence and furnished application blanks to about 18 or 20 Fellows a year, say 130 altogether. Of these 19 have been placed in the hands of the attorney of the Society with the following disposal:

	CASES
Verdict for the defendant.....	5
Settled.....	5
Suit withdrawn.....	3
No suit brought.....	1
Insurance Co., forced by atty. to defend suit..	1
Pending.....	4
Total	19
During this time the Society has expended for defence.....	\$2885.25
Average cost per year.....	412.00
(11+ cents per capita annually.)	

As will be seen, no case has been lost thus far. Although defence is provided only for suits brought, in practice many suits are prevented and others are dropped when the plaintiff learns that the Society stands behind its Fellows.

Under the terms of our act the president and secretary handle the malpractice defence. Application is made, usually by telephone, to the secretary, who makes a rough memorandum of the facts in the case for the malpractice files and sends the applicant a printed blank and a copy of the malpractice act. When the pa-

pers have been properly filled out and are returned with a written account of the case and a receipted bill for society dues, the president and secretary consider the circumstances, and accept the case if everything seems to be in proper form. The applicant is told that he may tell the plaintiff's attorney that the case has been placed in the hands of the Society. In the event of threatened suits this has the effect, in a majority of instances, of stopping the proceedings, and nothing further is heard of the threat, and this is the result in most of the suits that have been already entered, as is shown by the fact that but *three* suits have been actually placed in the hands of our attorney out of about *one hundred and thirty* (1 in 64-). considered. Grateful letters have been received from several Fellows who have been defended, and many who have been only threatened have expressed themselves as relieved of much worry of mind and apprehension.

If a suit is sent to our attorney the president and secretary select experts and the Society pays the necessary expenses of its experts, but no fees. The entire subject of malpractice defence was reviewed by a special committee of the Society, that reported to the Council, February 4, 1914, with recommendations. (See Bulletin No. 1, July 1, 1914, Pages 27-30).

Dr. C. M. Green *Moved*: That in cases wherein verdicts or settlements in favor of the defendant are secured, the defendant shall reimburse the Society to the extent of one-half the legal expenses incurred by it. The chair explained that there had been a recent case in which a Fellow was grateful for successful defence and at the suggestion of the president had paid half the cost of defence. On being put to a vote the motion was defeated.

Dr. W. P. Bowers called attention to a conflict between the dates of the meetings of the Massachusetts Medical Society and the American Medical Association next June. He moved and it was *Voted*: That the next annual meeting of the Massachusetts Medical Society shall be held in Boston, June 6 and 7, 1916.

He introduced the following amendment to Chapter II, Section 1, of the by-laws, and after being duly seconded it was adopted by a unanimous vote:

Section 1 of Chapter II shall be amended by transposing the words "unless otherwise ordered by the Council," in the second and third lines of the said Section, and by omitting all of the text after the word "June" in the fourth line, so that the Section as amended, will read as follows:—

The annual meetings of the Society, shall be held, unless otherwise ordered by the Council, in Boston, on the second Wednesday in June.

Dr. A. N. Broughton reported on his attendance, by the president's request, at the hearing given by the Industrial Accident Board in June, 1915, and suggested that the committee of the Society on the Workmen's Compensation Act should take some action to counteract a spirit manifested by the Board that is hostile to the interests of the profession. No action taken.

Adjourned at 1.30 p.m.

WALTER L. BURRAGE,
Secretary.

Miscellany.

CONTINUED RISE IN COST OF DRUGS.

IN previous issues of the JOURNAL we have noted from time to time a continuous rise in the cost of various drugs owing to circumstances attendant upon the European War. Report from New York on September 24 states that this general increase of price has continued, affecting particularly quinine, opium, and the various botanical drugs.

"A fresh advance of 4 cents per ounce is announced by all domestic manufacturers of quinine, bringing prices to a minimum of 40 cents per ounce for quinine sulphate in 100-ounce tins. This represents the highest price, with but one exception, reached by quinine since 1889, a period of twenty-six years. The demand for quinine from the European belligerents has been unabated since the war started, cable inquiries for quantities ranging from 25,000 to 50,000 ounces having been received here periodically since the first of January. The continued strengthening of the market for quinine to a point where prices are today, 14 cents per ounce higher than at the beginning of the European War, has been based partly on the strong statistical position of the article, but is traceable more generally to a gradual elimination of all competition from German and English makers. The latter interests have been hard pressed to supply their own abnormal requirements, with the result that they have been forced into this market.

"Cinchona bark, from which the active principal of quinine is extracted, had been arriving here in normal volume up to the beginning of 1915. Imports for twelve months ended June 30 last totalled 3,944,549 pounds, valued at \$561,106, against 3,648,868, worth \$464,412, in 1914 and 3,553,239, valued at \$357,490, in 1913. Shipments of this bark from Java to Europe have recorded a marked slump within the past eight months, however, total shipments to Europe from January to August having been 6,523,760 Amsterdam pounds, against 10,318,000 Amsterdam pounds for the same time in 1914. A pronounced falling off in the imports of quinine sulphate from Germany, which country had been the mainstay of European consumption, has also been shown, and imports of English-made sulphate have also been negligible. Total imports of foreign sulphate in the year ended June 30 last were 1,829,732 ounces, of the value of \$452,348, against 2,879,466 ounces, valued at \$624,125, in 1914, and 3,185,984 ounces valued at \$562,924, in 1913. Since Jan. 1, 1915 the imports of foreign sulphate into the United States have been relatively unimportant.

"The above statistics are particularly illuminating, inasmuch as they indicate that, while arivals of cinchona bark have been within reasonable range of those of preceding years, the de

cline in imports of the sulphate and the exports of foreign sulphate in twelve months ended June last of 59,467 ounces, against only 172 ounces in the preceding year, have emphasized the fact that a much greater reliance has been placed upon manufacturers in this country. The latter interests now practically have the field to themselves. Whether they will be able to take definite advantage of the reduction in foreign production incidental to the war is doubtful, in view of the agreement existing between Java bark growers and European salts makers. The fundamental basis of this compact was the establishment of a minimum of 6.20 Dutch cents per sulphate unit on sales of manufacturing bark. In view of the above understanding there seems little likelihood that American manufacturers will be permitted to benefit at the expense of their European competitors once normal conditions are restored.

"Unabated buying by various European countries, particularly Russia, of all kinds of narcotics, anesthetics, anodynes, analgesics and disinfectant drugs has been seen in the wholesale drug and chemical market within the past fortnight. This has more than made up for the curtailed demand from domestic consumers, who have generally restricted purchases to small jobbing lots in view of the existing shortage which has kept values at practically prohibitive levels.

"Yesterday further advances were announced in the prices for gum opium to a minimum basis of \$8.25 per pound, for powdered to \$9.25 per pound, and for granular to \$9.50 per pound. The increase is based on the heavy export demand for such opium derivatives as morphine and codeine, as well as upon the poor outlook for 1915 crop in Turkish possessions and the great difficulties encountered in making shipments from the bombarded port of Constantinople to any other destination than Germany. Latest estimates of the Turkish opium crop indicate that not more than 3000 to 3500 cases will be produced. Another important feature in the opium situation is the recent advices from Greece indicating that practically the whole Macedonian crop of opium will this year be shipped to Great Britain, which will cut off the United States. Stocks of opium in bonded warehouses in New York on Aug. 1 last stood at 50,777 pounds against 68,652 pounds on July 1, indicating that over 17,800 pounds had been taken out of this market, presumably for export.

"A great scarcity of bismuth metal, as well as all bismuth preparations has lately developed in the domestic markets owing to a sharp curtailment of the production of bismuth metal in Mexico and a heavy curtailment of imports from other importation points. Domestic manufacturers of bismuth preparations have not been offering other than small amounts for the past three weeks. They are still quoting \$2.65 to \$3.00 per pound for metallic bismuth, but sales have been consummated all the way from

\$5 to \$6 per pound by second hands. The export demand for all varieties of bismuth has been enormous and is still very heavy. It is stated that stocks are still too limited to enable them to supply ordinary trade requirements.

"One of the recent developments carrying more than usual interest was the advance in price of acetate of lime from a basis of \$3.50 and \$3.55 per hundredweight, to a basis of \$4 and \$4.05 per hundredweight. This was brought about by the unusually heavy demand for its by-products, acetone and acetic acid. It is said that there are less than 100 tons of domestic acetone not contracted for today. One recent heavy export order for several thousand tons was flatly refused owing to the dearth of stocks. The demand for acetone from munitions manufacturers has been particularly heavy, while the demand for acetic acid has been large because of the increased operations of domestic as well as English manufacturers of dyestuffs. The shipments of acetate of lime have been pared to the quick in order to permit of the increased export business in acetic acid and acetone. Thus for twelve months ended June 30 last the exports of acetate of lime amounted to but 24,673,247 pounds against 68,160,224 pounds in the corresponding period last year and 80,579,838 pounds in the same time in 1913.

"Such changes as have appeared here among the botanical drugs have again been upward, but movements in the botanical drugs have possessed little more than nominal significance as stocks have become so limited that purchases have been restricted to small jobbing quantities. Kola nuts, sassafras bark, soap bark, juniper berries, vanilla beans, cannabis indica, sage and thyme leaves, gentian and rhatany roots, caraway, coriander, mustard, poppy, anise and celery seed, marjoram and savory leaves, belladonna, aconite, burdock, alkanet, German dandelion roots, sloe berries, horehound leaves and quince seeds have all been marked up owing to increasing scarcity. The general situation in botanical drugs offers no hope for replenishment of standard products so long as the war continues. Italian participation in the war prevented the promised outlet for some of the German and Austrian products. Botanicals of Spanish and Italian origin have appeared here, but these have been lacking in quality and have not appealed to the general consuming trade. The question of substitution has come in for a deal of attention. In the case of belladonna leaves, which enter into a distinctive field of consumption, substitution is out of the question, and for the small lots obtainable here \$1.75 and \$2 per pound is asked, comparing with a price of 50c per pound about a year ago."

Further report from New York on October 6 notes the continuance of the phenomenal rise in the cost of quinine and other drugs.

"The sensational advance in quinine to 90 cents and \$1 an ounce marks the highest price within the memory of many members of the

New York wholesale drug trade. Practically all domestic manufacturers of quinine have withdrawn all future offerings, and many of them may be forced to cancel outstanding contracts in view of a shortage of the basic material—cinchona bark. Early this year manufacturers were accepting business in quinine on the basis of 26 cents an ounce. Prices were gradually advanced until a 40-cent an ounce basis was established a few weeks ago.

With the withdrawal of practically all makers from the market, the speculation among second hands has become intense. Coupled with this are the continued export inquiries for the article, these amounting in many instances to 25,000 and 30,000 ounce lots. The sharp advance in quinine to 90 cents and \$1 an ounce discouraged the exporters, however, who state that the London party, where best Continental brands of quinine are obtainable at two shillings one penny an ounce, is lower than the American. Some specialists, who have long been interested in the exportation of the article, state that only in one previous instance has the present value of quinine been exceeded and that twenty years ago when speculators succeeded in inflating the quotation to \$6 an ounce. So far as the makers are concerned, the highest price ever exacted by them was in 1886 when the market was on a 73-cent an ounce basis.

The present extraordinary situation in quinine, which is one of the most important drugs in general usage today, grows out of the reported inability of domestic makers to procure anything like sufficient quantities of cinchona bark out of Amsterdam to supply them with crude material. It is said that London and the continental makers of quinine have succeeded in cornering the cinchona bark market. In connection with this situation it is of interest to note a drop in imports of cinchona bark for the year ended Aug. 1, 1915, to 3,388,920 pounds, which compares with 4,009,635 pounds in 1914 and 3,314,359 pounds in 1913. The imports of foreign sulphate of quinine during the period mentioned fell off to 1,862,056 ounces against 2,717,160 ounces in the corresponding period in 1914, and 3,177,873 ounces in 1913.

CASES OF INFECTIOUS DISEASES reported to the Boston Board of Health for the week ending Oct. 11, 1915, are as follows: Diphtheria, 39, of which 1 was non-resident; scarlatina, 16, of which 3 were non-resident; typhoid fever, 13, of which 3 were non-resident; measles, 7; tuberculosis, 49, of which 6 were non-resident. The death rate of the reported deaths for the week was 14.04.

CENSORS' EXAMINATION.

The Censors of the Suffolk District Medical Society will meet to examine candidates for admission to the Massachusetts Medical Society at 8 The Fenway, on Thursday, November 11, 1915, at 2 P.M.

Candidates, who must be residents of the Suffolk District or non-residents of Massachusetts, should make personal application to the Secretary and present their medical diplomas at least three days before the examination, between the hours of 4 and 5 P.M.

DAVID CHEEVER,
Secretary.

355 Marlboro St., Boston.

APPOINTMENTS.

Dr. Harold K. Faber of the Rockefeller Institute for Medical Research, has been appointed assistant professor of pediatrics at Stanford University Medical School.

Dr. Frank A. Hartman has been appointed lecturer in physiology at the University of Toronto.

RECENT DEATHS.

DR. CHARLES R. CROSS, JR., of Brookline, Mass., died on October 8 in a military hospital at Dinard, France, in consequence of a fractured spine received on October 6 in an automobile accident. Dr. Cross, who had been on service during the summer with the Serbian Red Cross, had recently come to Paris and engaged in relief work at Dinard.

DR. FRED L. HIGGINS, who died recently in East Boston of heart disease, was born at Hanover, Mass., in 1865. He had practiced dentistry in Rockland, Mass. and in East Boston.

DR. HOMER G. NEWTON, who died recently at Shelburne, N. Y., was born there in 1835. He graduated from Yale in 1859, and served throughout the Civil War as an army surgeon. Subsequently he settled in Brooklyn, N. Y., where he became known as a leading ophthalmologist, and was one of the founders of the Brooklyn Eye and Ear Hospital.

DR. ALTON E. OLIVER, formerly of Braintree, Mass., died on June 7, 1915, at Hankow, China. He was born at Braintree on September 2, 1883, and graduated from the Tufts Dental School in 1906. Immediately thereafter he went to China on the Red Cross service, and since the close of the Chinese revolution, has been practicing his profession in Hankow.

DR. SAMUEL CHASE THAYER, who died of pneumonia on October 11, at Boston, was born in Waterville, Me., on January 15, 1861. He received the degree of A.B. from Colby University in 1879 and that of M.D. in 1882 from the Bowdoin Medical School. He immediately settled in Boston where he had continued active in the practice of his profession until his death. He is survived by his widow.

I.

NON-TUBERCULOUS CASES IN THE STATE SANATORIA.*

By ELLIOTT WASHBURN, M.D., RUTLAND, MASS.

ARE there such cases in the State Sanatoria and, if so, is their number sufficiently large to be a matter of any especial importance in view of the fact that the waiting list of applicants for admission is so long that sometimes favorable cases become unfavorable before it is possible to admit them?

In short, are we caring for any cases which, because they are non-tuberculous, ought not to be in the sanatoria?

When the Rutland Sanatorium was established nearly seventeen years ago and somewhat successful efforts were made through examina-

tions by special, skilled examiners to restrict admissions to very early and favorable cases, it was not uncommon to hear the remark even from physicians, "So and so was cured of consumption at Rutland—I wonder if he really had it?" To-day we still try to reserve Rutland for early cases in adults. In addition we have at Lakeville, North Reading and Westfield a large number of advanced cases in adults while at Westfield we have also about 150 children in all stages of the disease. Therefore, our search for the non-tuberculous must be made in adults and children admitted as presumably in all stages of the disease.

Off-hand it would seem that the chance of error in diagnosis in well-advanced or far-advanced pulmonary tuberculosis either in adults or in children ought to be small. Probably it is, and yet, on the other hand, Dr. Ash, pathologist of the Boston Consumptives' Hospital at Mattapan, reported that although that institution is intended for the care of the tuberculous only, and that most of the cases are far advanced, in 198 autopsies at that hospital 23 cases or 11.5% of all cases which came to autopsy proved to be non-tuberculous. In these 23 cases it was found that instead of tuberculosis the true conditions were pneumonic sequelæ in eight instances, chronic cardio-renal in five, septicaemia in two, aneurysm of the aorta in two, malignant disease of the lung in five and actinomycosis in one. He stated that 353 autopsies reported from eight institutions in this and other states caring for a similar type of cases of tuberculosis showed 38 or 10.8% non-tuberculous.

* Read before The Massachusetts Medical Society, June 8, 1915.

If this percentage of variation or error, if you please, in diagnosis can be accepted as fairly true and constant in patients admitted to special hospitals as advanced in tuberculosis, may we not well ask "What is the percentage of variation in cases which are admitted as early or incipient cases—in which the true diagnosis is admittedly more difficult than in the advanced types?" Some patients come in with very vague symptoms and signs "pointing to tuberculosis"; their sputum, if they have any at all, is persistently negative; they have little or no cough; Von Pirquet may be negative or positive; after a short time their vague symptoms and signs clear up and they go home. Who shall definitely say that they were tuberculous or that they were non-tuberculous?

I shall leave to others who are to read and discuss the papers of the afternoon the consideration of the errors of diagnosis in supposedly advanced cases in adults and in all stages of the disease in children. At Rutland cases are supposed to be early and favorable at least on admission. In passing it is to be deplored that any attempt to study the question in our State Sanatoria is almost insurmountably handicapped by our utter lack of autopsies to verify or to disprove our clinical diagnoses. Without them it is hard to make statements with any degree of authority.

Up to June 1, 1915, there were admitted to Rutland 10,361 patients as presumably in the early stages of consumption. Of this number 1651 were discharged as "not considered" because from nostalgia, discontent, inability to adjust themselves to sanatorium conditions, family reasons or other causes they elected to remain less than one month. I have found records since December 1, 1909, taking this five and a half year period as being probably typical of the whole seventeen years of the sanatorium's life, of 20 cases which were discharged as probably non-tuberculous. Of this number, only four remained more than two months; in other words, in these four instances it required more than two months even with our special skill and facilities before we could be reasonably certain that these cases were non-tuberculous. These cases demonstrate that the physician who states positively, as some do, on one examination, that a patient is non-tuberculous is, to say the least, exposing himself somewhat broadly to the possibility of error. At the present time we have several cases in the sanatorium which we are coming to believe are non-tuberculous.

Is it fair to assume that these twenty cases were really all the non-tuberculous cases which were residents in the sanatorium during the stated period? Who shall say? We have no autopsy findings: approximately 35% of all our cases at Rutland have negative sputum or no sputum at all during their entire sanatorium residence; until recently no Wassermanns have been made and even now we are just arranging the details necessary to make routine Wasser-

manns on every patient upon admission; the Von Pirquet test is not infallible. Personally, I feel somewhat strongly that this is not the number of the non-tuberculous during this period. But—who knows? Given certain cases with vague symptoms, signs and unsatisfactory tests one competent observer will say, "They are tuberculous," and another equally competent will say, "Well, they may be, but I do not believe it." Accordingly they are recorded as tuberculous or non-tuberculous, according to the personal equation of the one observer or the other.

In the early stages of this disease the symptoms and signs may be very indefinite. The symptoms are those which may be found in other diseases: the signs may not be sufficiently pronounced to make possible the positive statement that they are those of pulmonary tuberculosis to the exclusion of other diseases affecting the respiratory organs which may have signs somewhat simulating those of early consumption. The chance of confusion or even of error is by no means small. Take, for example, the following which was one of the cases included in the twenty mentioned:

A lad of 15 with a history of old asthmatic attacks for years during and following which he had cough and expectoration, each attack lasting for 36 to 48 hours. On admission he had dullness at the right apex—whistling râles heard over both lungs, particularly over bronchial area—a few clicks at right base—doubtful atelectasis—practically the findings of chronic emphysema. Sputum persistently negative. Von Pirquet negative. Highest afternoon temperature during sanatorium residence 99.4. Discharged after six months as doubtfully tuberculous; right apex still dull.

Eight cases of the twenty presented to us neither history, symptom nor sign of pulmonary tuberculosis nor indeed of any other disease which we could determine. Beyond the fact that they appeared a little run down from occupational or other non-disease causes and that they recuperated rapidly in the short time under our observation, there is nothing to say about them. These cases were kept for periods of from two weeks to four weeks because they were sent in by fairly good men in deference to whose opinion in sending them in at all we kept them until we were reasonably sure that they were non-tuberculous.

One anemic and extremely neurotic young woman presented no valid evidence of tuberculosis.

A man, 37, sent in by a competent observer, suffered from nervousness and from chronic laryngitis which may have been due to his occupation that of iron moulder involving exposure to extremes of temperature and to dust. At all events we did not deem it to be tubercular in its nature. His general condition was impaired; no signs of pulmonary disease; temperature normal throughout sanatorium residence of one month. Improved markedly in general and in laryngeal conditions. Discharged as non-tuberculous.

A man, 41, dullness and somewhat rough inspiration at right apex; no distinct râles heard; no elevation of pulse or temperature. Complained of cough but was not heard to cough. Sputum and Von Pirquet negative. Discharged as non-tuberculous or at least with no active tuberculosis.

A woman with dullness at both apices; all other signs and tests negative during sanatorium residence of one month. Somewhat doubtful history of previous pulmonary disease; discharged as non-tuberculous or very doubtfully tuberculous.

A man highly neurotic but negative as to pulmonary tuberculosis.

A young man of 20 with a history of a fall one month previous to filing application for admission, which wrenched his right chest. Admitted with dullness at right apex with moderate number of râles. Highest sanatorium temperature 99.2. Sputum and Von Pirquet negative. Râles were heard at first but all symptoms rapidly disappeared. Tuberculin test six weeks after admission was negative, no reaction whatever. Discharged as probably non-tuberculous.

A young girl of 17 admitted pale, thin and run down but with absolutely no signs that we could detect of pulmonary tuberculosis. History of close contact for long periods with two tuberculous sisters. We found no active tuberculosis but may have been a so-called pre-tuberculous case. She made marked improvement during her stay.

Man, 27, who showed on admission slight pleurisy at left base anteriorly which cleared up entirely in a few weeks. He claimed to have had positive sputum in March, 1913. We found no positive signs of pulmonary tuberculosis and his sputum was persistently negative during his sanatorium stay. In September, 1913, Von Pirquet negative.

A case showing no temperature, no elevation of pulse rate, no cough, negative sputum, had slight dullness at right apex and positive Von Pirquet skin reaction but after six weeks' observation was discharged as probably non-tuberculous.

One case admitted with dullness and râles at left base which slowly cleared up was discharged after two months as non-tuberculous. This was believed to be an undoubted case of unresolved pneumonia.

A case which had been under observation at a Day Camp for several months was discharged after four weeks as probably non-tuberculous. We found absolutely no signs of pulmonary disease although he had a weak heart action without abnormal sounds.

A woman with dullness but no râles at right apex. Tired very easily; did not react to Von Pirquet tuberculin test; sputum negative; pulmonary examination negative; discharged as non-tuberculous.

The following case is now under our observation:

A young woman, 22, admitted from the Massachusetts General Hospital on May 11 with the following notes taken at that hospital:

"Admitted Massachusetts General Hospital April

29, 1915. History of fainting spells. Has had gastric distress and dyspnoea for a week but no other respiratory symptoms or symptoms of tuberculosis. Has lost eight pounds in weight.

"Left chest full of fluid displacing heart markedly to the right.

"Left back shows broncho-vesicular breathing. Dull with diminished bronchial voice.

"X-ray on April 21. Left chest is dull as high as clavicle. Heart and trachea displaced to right. Both apices appear normal. Pathological process in left chest which may be fluid or tumor. The marked displacement of heart and trachea without complete dullness of left chest suggests mediastinal tumor.

"Tapped April 21 and 42 ounces of clear, yellowish fluid removed.

"Tapped again April 22 and 20 ounces more removed. Much more remains.

"X-ray on April 24. Lower half of left chest is dull. Dullness rises higher in axillary than medial line. No positive evidence of phthisis. Heart shadow within normal limits. Fluid in left chest.

"Tapped again April 27—eight ounces removed, all that could be obtained. Temperature coming down.

"Wassermann and Von Pirquet negative. Sputum negative as to tubercle bacilli.

"May 11, transferred to Rutland."

This case is now under our care. There is evidence of a small amount of fluid in the left chest; she runs a little temperature but is improving in her general condition. Unless we accept the dictum that all wet pleurisies are tuberculous, we would lean to the opinion that she is non-tuberculous. She may be one of those cases whose tuberculosis first becomes readily apparent to the ordinary practitioner about two years or so after the initial pleurisy. Time alone will tell.

Beside this case we have in the sanatorium at this writing two other cases of which we are in doubt; with symptoms, signs, tests and histories so uncertain that we hesitate to classify them. And yet if they are not tuberculous what is their disease? Border line cases in diagnosis.

We have no record at Rutland of any case which we deemed to be solely syphilitic although we have had, and have at present, cases which to us are undoubted cases of pulmonary tuberculosis which gave very definite histories and tests for syphilis. One case in particular has been of interest to us as he presented what we deemed to be unquestionable signs of well advanced tuberculosis in both lungs with sputum which was repeatedly positive. His Wassermann was positive and a well known syphilographer was quite strong in his belief that the case was one of syphilis rather than of tuberculosis, in spite of the positive sputum and pulmonary signs which to us appeared so indicative of tuberculosis. He has been under our observation at intervals for three years.

We have no record of any case which we considered to be solely one of malignant growth although we have just discharged a woman who, during her sanatorium residence was operated

upon for a breast growth which the pathologist reported to be benignant. She was without doubt tuberculous.

These cases illustrate fairly well the nature of the cases which after careful consideration we at Rutland have deemed to be non-tuberculous. The percentage of our admissions in the period stated, namely since December 1, 1909, so considered, is so small that it appears to warrant the statement that after all it is not a matter of especial importance in connection with the question of their right to be in the sanatorium. Autopsy findings if they were available might reverse or markedly modify this belief but in their absence we are necessarily bound by our clinical findings.

Whether this small percentage at Rutland holds true in the other sanatoria which have to deal with many more far advanced cases than does Rutland, their own medical staffs will discuss.

II.

ERRORS IN THE DIAGNOSIS OF CHRONIC PULMONARY DISEASE.*

By JOHN B. HAWES, 2d, M.D., BOSTON.

THE diagnosis of incipient tuberculosis is by far the most difficult and likewise the most important problem which confronts us in the anti-tuberculosis campaign. When the disease has progressed beyond the early stages the diagnosis is usually only too evident. Each one of us, however, occasionally meets with patients who have marked signs of pulmonary disease very suggestive of tuberculosis which later on, usually to our surprise and often to our chagrin, turn out to be due to something else. It is quite unfair to these patients to stamp them at once as advanced consumptives. It is unfair to our sanatoria and hospitals to admit such patients as these while our waiting lists are crowded with real consumptives in urgent need of treatment for themselves and of isolation from others. This paper is based upon a series of such patients who have been sent to me as probable cases of pulmonary tuberculosis. In each of them I have been forced to the conclusion that the disease was not due to tuberculosis, but to some other cause. This study of these patients has brought out many interesting and valuable points, and has, I hope, made it less easy for me to make the same mistakes in the future that I have made in the present instances. These cases involve the differential diagnosis between pulmonary tuberculosis and cancer, syphilis, and so-called influenza infections. I shall present the important features of each case briefly, and then take up the more striking points in diagnosis.

CASE 1. W. C. H. The patient is a married man of 40, a teacher by occupation. His aunt and first wife died of tuberculosis. His previous history is negative, except for an occasional attack of grippe.

* Read before The Massachusetts Medical Society, June 8, 1915.

In June, 1904, shortly after his wife's death, when he was very much tired out, an excellent diagnostician found indefinite signs in his lungs. He evidently suspected tuberculosis. This suspicion was confirmed shortly after by a prominent lung specialist. Of fifteen sputum examinations, one was said to have been positive. This was made, however, in the out-patient department of a large institution where many other examinations were constantly being made. His doctor advised him to keep on at his work as principal of a large high school, which he did for two months when he went to a private sanatorium in Rutland. During this time, many sputum examinations were made, none of which was positive. He went back to his work as a school superintendent in 1905, a year later, and has worked steadily ever since without symptoms until recently.

About May 1, 1914, he began to feel rather tired and run down and noticed a slight cough. A local physician told him that his old trouble had broken out again and was rather pessimistic as to the future. He advised him to take one year of absolute rest in a different climate. This advice was confirmed by his own family doctor.

When I first saw him, September 5, 1914, he felt perfectly well except for slight weakness. He had a very slight cough, with a little sputum in the morning. Physically he was a large, strong, healthy-looking man weighing 207 pounds, with normal temperature, a low pulse, and a blood pressure of 130. At the base of the left lung there was moderate dullness with slightly diminished breathing, and numerous râles of all kinds in the axilla and back below the scapula. There were no râles elsewhere. In spite of the one sputum examination which was said to have been positive in 1904, I was unwilling to believe that this was tuberculosis. He was seen by Dr. W. H. Smith of Boston, who agreed with me. The Wassermann test was negative. The x-ray by Dr. Walter Dodd showed "certainly no positive evidence of tuberculosis, empyema, or lung abscess." There was a negative reaction to old tuberculin in doses of 1/10 mg., 1 mg., and 10 mg. given subcutaneously. Sputum was negative for tubercle bacilli, but contained many organisms resembling those of influenza. The patient was advised to go back to his work as a school superintendent and to lead a normal healthy life. This he has done, and has been perfectly well ever since. At present, with the exception of a few sticky râles after cough, his lungs are normal.

It is possible that this case may have been, and still is, one of tuberculosis. Personally, I think that the repeated negative sputum examinations, despite the one which was said to have been positive, and the negative subcutaneous tuberculin test is the strongest possible evidence against tuberculosis. It seems to me that it would have been a grave injustice to have made this man give up work for a year, to have sent him to a sanatorium, and to have practically condemned him to an invalid or semi-invalid life for a long time to come. On the other hand, it is certainly quite unsafe for him to forget altogether the fact that he has been distinctly under suspicion. A case of this kind should report regularly every four or five months for examination, no matter how well he may be feeling. As to the exact diagnosis, I should be inclined to call it chronic

influenza, although I must admit that influenza has become somewhat of a general term covering various non-tuberculous lesions.

The second case resembles the first in many respects.

CASE 2. P. K. This man is a teacher 48 years old. His mother, father, wife, and one sister died of tuberculosis. Until he reached the age of seven years, he was considered rather delicate; after that, perfectly well. He was about five pounds under weight when I saw him. Two years and a half ago, his wife died of tuberculosis after a two years' illness. The patient slept in the same room and in the same bed during the greater part of the time.

Last summer, in 1914, while in camp, he was taken with sudden pain and oppression in the chest, with cough and yellow sputum. He came home and saw Dr. Irving Fisher of West Newton, who found very little in his lungs. When I saw him, in September, 1914, except for the fact that he did not feel quite so strong as usual, he was in very good condition. He had a moderate cough with yellow sputum. He came for an examination in order to rule out tuberculosis. He, himself, felt fairly well.

Physical examination showed a strong, healthy-looking man, with normal temperature and pulse, weight 162. Blood and urine were normal. Sputum shows no tubercle bacilli, but many influenza bacilli and pneumococci. Near the base of the right lung, in the axillary line over an area of two and a half inches in diameter, after a cough only, there are showers of fine râles. There was no change in breathing or vocal fremitus here or elsewhere. X-ray report by Dr. Walter J. Dodd states as follows: "In the region between the second and third interspace on the right, there is an irregular dense area which is probably an extension of a process from the root of the lung. The apices do not seem to be involved. This may perfectly well be tuberculosis, but we do not feel justified from this evidence alone in stating so positively." My last note on this patient was dated February 13, 1915, when he stated that he was perfectly well in every way without cough or other symptoms. The lungs were perfectly clear.

This case very much resembles the first one in that there was a very marked and prolonged exposure to tuberculosis along with constitutional and local signs and symptoms which might perfectly well be due to that disease. On the other hand, as in the first case, I felt, as I always feel, that in diagnosing a process at the base of the lungs, the burden of proof is distinctly on the doctor to show that it is tuberculosis and not something else. Here, again, it would have been perfectly easy to have railroaded this man to a sanatorium or to have put him on a strict regime which would have made an invalid of him for one or two years.

I do not like to call such cases chronic influenza. Dr. F. T. Lord would, I believe, classify this case and the first one as a chronic pneumonitis which may or may not be due to the influenza bacillus, in this case probably not.

CASE 3. E. S. This patient was a clergyman 48 years old. His family history shows no direct

exposure, although six aunts died of tuberculosis. He had had a suppurating middle ear off and on for many years. In 1905 he had an attack of so-called intercostal neuralgia which, on questioning, seemed to me more likely to have been a pleurisy. In 1907, he was very much run down, and had enlarged glands on the right side of his neck. He was in the Massachusetts General Hospital at this time where his case was diagnosed as one of tuberculous cervical adenitis.

I first saw him November 8, 1914, at a sanatorium in New Hampshire. He told me that in the early spring of this year he developed a cough with a fever, and began to lose weight and strength. He was placed under fairly rigid home treatment for a few weeks, and was then sent to a nearby sanatorium. At the time I saw him, he had a harrassing cough with very little sputum. No tubercle bacilli were found on repeated examinations. He never raised any blood. Extreme weakness was a striking feature. On examination, I found a temperature of 101, pulse of 120, moderate secondary anaemia, normal urine, and a blood pressure of 130. The patient was well developed with flabby muscles. There were some cherry-sized glands in each axilla. There was slight dullness at each apex with a few crackles after cough on the right. On the right side, from the third rib downward, there was dullness becoming flatness, with diminished breathing, and many sticky râles before and after cough. At the extreme base the râles were not so numerous. My diagnosis at this time was tuberculosis of the right apex, thickened pleura, and a tuberculous pleurisy with probably a little fluid on the right side.

A month later the patient left the sanatorium and came to Boston. His constitutional symptoms were still marked. The lung showed increased dullness, fewer râles, and a heart displaced to the left. In the right scapular region, there was distant bronchial breathing and whispered voice. X-ray showed nothing except an intense shadow over practically the entire right lung with the heart slightly to the left. I tapped his chest one and one-half inches below the angle of the scapula on the right, but obtained nothing. I then began to feel sure that this case was not one of tuberculosis. He was seen in consultation with me by Dr. W. H. Smith, who agreed as to the probable non-tuberculous nature of the process. We both felt that a concealed pocket of pus was the most likely diagnosis. I then asked Dr. Wyman Whittemore to see this patient with a view to operation. After further study and observation, we decided to operate in order to rule out a possibility of any hidden pus. The operation revealed a curious friable mass of solid material occupying the greater part of the right pleural cavity. This, on examination by Dr. James H. Wright, turned out to be malignant disease, probably hypernephroma. The patient died shortly afterwards.

This case has many interesting features. I do not see how anyone, in the early stages of this process, could have made any other diagnosis except pulmonary tuberculosis. Later on, however, the points against tuberculosis became more evident, namely, the increasing signs of disease in the lungs with a small amount of sputum, and the absence of fluid. Without operation, I doubt if the correct diagnosis would have been reached. His stay at the sanatorium certainly did no harm, as the outcome was inevitable in

any case. In a recent talk with Drs. Baldwin and Kraus of Saranac Lake, I find that they have had three or four of these cases of hypernephroma at Saranac during the past few years. There is one patient there at the present time in whom this diagnosis has been made. In no other instance, however, was the diagnosis made except at post-mortem. I think this condition an extremely difficult one and oftentimes an impossible one to detect, at least in its early stages. It should be borne in mind, however, as a possibility whenever there is marked weakness, grave anemia, and extensive signs in the lungs out of proportion to the cough and the amount of sputum raised.

The next three cases are those which are usually called influenza processes. This, as I stated before, has come to be a general term for a more or less subacute non-tuberculous infection of the pleura and the base of the lung.

CASE 4. P. C. This patient was a young Italian of 20. His family history was excellent and his previous history negative. He felt perfectly well until three weeks ago when he was suddenly taken with a dizzy spell, some fever and loss of appetite. He had a slight cough. He improved slowly in general condition but continued to cough and to raise yellow sputum.

Temperature and pulse were normal; he was about 10 pounds under weight. There were a few crackles and slightly increased signs at the right apex, and many sticky râles, with moderate dullness up and down the entire left chest before and after cough. The sputum was a thick greenish pus full of bacilli resembling those of influenza. This condition in his lungs continued for a few weeks, but finally cleared up, leaving only occasional dry râles in the left axillary region. His weight returned to normal.

CASE 5. R. S. This patient is a lawyer 42 years old, with an excellent family history. He was said to have had pulmonary tuberculosis as a child. On June 12, 1914, when feeling perfectly well except for the fact that he was more or less tired out, he was suddenly taken with an acute grippy attack, accompanied by a slight cough, a fever of 101, and a rapid pulse. When I examined him at this time, I found at the base of the right lung dullness, diminished breathing, and numerous sticky râles. This condition continued for a few weeks, with slight evening fever, rapid pulse, and every sign, constitutional and local, of a beginning tuberculous process at the base of the lung. Repeated sputum examinations, however, showed no tubercle bacilli but many bacilli resembling those of influenza, and a few pneumococci.

Gradually this process cleared up so that at present, with the exception of slight dullness, the lungs are perfectly normal, and the patient's general condition is as good as it ever was.

CASE 6. D. W. This patient is a strong healthy young shipping clerk of 23. His family history and habits are excellent. His past history is not unusual. On March 27, 1915, he first noticed pain in the right side of his chest, worse on walking or on breathing, so that he could take only short breaths. There was some cough and sputum. Two weeks later, he raised some blood mixed with saliva. When

I saw him, aside from slight pain in his chest, he felt perfectly well and said that his strength, appetite, etc., were normal in every way.

On examination, I found a normal temperature, a pulse of 70, and weight nearly up to normal. He looked perfectly well. At the base of the right lung, there was moderate dullness with numerous sticky râles; the apices were clear, and the heart was in normal position. The sputum was a yellowish pus with numerous organisms resembling those of influenza. No tubercle bacilli were found. Two days later, over the dull area signs of consolidation became evident with intense bronchial breathing, bronchial whispered and spoken voice over the lower lobe on the right. His temperature reached 99.4 at one time, but aside from this, was perfectly normal.

I placed him in a hospital under observation. After two or three days of normal temperature, I put him through a subcutaneous tuberculin test. The only sign pointing to a reaction of any kind was a rise in temperature up to 100.6. Constitutional signs and symptoms of a reaction were of the slightest, and there was no change in the suspected area in his lungs. I considered this a negative reaction as far as the process in the lungs was concerned. The temperature came down to normal and has been so ever since. The pulse stayed between 70 and 85. The lungs gradually cleared up, so that a few weeks later they were normal in every way.

These three cases are to me distinctly puzzling. In one of them, Case 5 (R. S.), there was a past history of tuberculosis. In the last one, there was a history of spitting of blood. In each instance, as far as the signs in the lungs were concerned, tuberculosis had to be seriously considered. Had it been impossible to put these patients under careful close observation, or had their mentalities been of a type which required an immediate definite and categorical answer as to whether they did or did not have pulmonary tuberculosis, I feel that I probably would have said in each instance as a result of my examination alone that the chances were in favor of tuberculosis and that the patient should go to a sanatorium or elsewhere. This certainly would have done no harm, and the result would have been a brilliant and rapid cure that would have enhanced the sanatorium records. I am extremely thankful that I did not do this. Exactly what was going on in the lungs and how important a factor the organisms resembling influenza were in this process, I am not prepared to state. I do feel, however, that there are many patients who are called tuberculous and who are sent to sanatoria, who belong to this class.

CASE 7. T. P. This patient is an Italian of the lower class, 38 years old, born in Italy. There was a definite history of exposure to syphilis, although I could obtain no history of any lesion. He came to the Massachusetts General Hospital stating that a year and a half ago he began to have coughing and choking spells so that breathing was very difficult. He felt as if there were a constriction under the lower part of his sternum. These attacks came once a month, associated with pain in the back. He weighed 175 one year ago, and weighs 128 now. He has been getting progressively weaker, and has done

no work for a year. At the present time he has a normal temperature and pulse. He has evidently lost much weight. The right pupil is irregular, and is smaller than the left. They both react, though sluggishly. There are a few pea-sized glands in the neck. The lungs show poor resonance all over, especially at each apex, more on the right than on the left. There is high-pitched expiration, with expiratory, sibilant, and sonorous râles all over. The signs are increased at the right apex. There is no interscapular dullness, the d'Espine sign is negative, and clinically no other evidence of mediastinal glands or other tumor.

The x-ray taken April 27th, showed dense masses of glands at both lung roots and a slight dilatation of the aortic arch. The heart is slightly enlarged to the left. Dr. Dodd reports the picture as rather suggestive of tuberculosis. The Wassermann reaction, according to the laboratory report, is suspicious. Sputum examination is negative. On this patient's first visit to the hospital, the signs of an active process in the lungs were confined to the right apex; while on the second visit, they were scattered over each lung.

The exact diagnosis in this case has not yet been made, but it is believed that it lies between syphilis and malignant disease, probably the former. There is certainly sufficient evidence of a luetic infection to justify placing him under rigorous treatment. Were this patient seen under circumstances where an x-ray examination and a Wassermann test could not be obtained, the diagnosis of pulmonary tuberculosis would be justified. He represents another type of case which can probably be found fairly frequently in any large sanatorium.

CASE 8. E. A. S. The patient is a post office clerk, 38 years old. The family history is excellent. He said that he had never been robust and had always been subject to frequent attacks of bronchitis. His maximum weight was 137 pounds 14 years ago; present weight, 119 pounds. He has been exposed to syphilis, but denies ever having contracted it. Twenty years ago, when 18 years old, he went to work in a factory where, owing to dust and his own tendency to repeated colds, he went rapidly down hill. He has been a letter carrier for the last ten years.

Eight or nine years ago, he had a right-sided pleurisy and has had symptoms in his right side ever since. Tuberculosis has been strongly suspected, but never definitely diagnosed. Two years ago he was sent to Denver, Colorado, where the physicians were unable to confirm the diagnosis of tuberculosis. The sputum was constantly negative, and there was no fever at any time. Despite this, however, he was given tuberculin for three months without any reaction. He returned to work in New York State as a post office clerk four or five months ago. He gave a history of at times having had large amounts of fairly liquid sputum which would flow out of his mouth night and morning on stooping over. This was brownish, often a reddish color, but never of an especially foul odor. When I first saw him, September 23, 1912, he had a recent cold, and had raised rather more than usual, although never in recent months so much as at times previous. He is very easily out of breath; his strength and appe-

tite are poor. He has seen many doctors all over the United States who have given as many different opinions as to his condition.

The patient is fairly well developed, very poorly nourished; his color is good. He is a sparely-built man of the wiry type. His temperature is normal; pulse, 74; weight, 119 pounds. The blood is normal. The urine contains the slightest possible trace of albumin, but nothing in the sediment. Blood pressure is 134. The sputum, of a brownish red color, showed a variety of organisms, but no tubercle bacilli. There is considerable arteriosclerosis with visible pulsation of the arteries. The heart is slightly pushed over to the left; otherwise it is normal. On examination of the lungs, I found what was evidently a compensatory emphysema of the entire left chest with harsh prolonged expiration everywhere. There were signs of extensive disease over the entire right chest with dry, fine, sticky râles everywhere below the fourth rib. Under the second and third ribs, near the sternum, was amphoric breathing easily noticed with a stethoscope or naked ear. The back shows signs similar to those in the front. On subsequent examinations, although the signs were changed to some extent here and there over the right side of the chest, the general features remained the same.

I was quite unable to come to a definite diagnosis, but merely felt very certain that the patient did not have tuberculosis. He was seen by Dr. W. H. Smith who likewise could come to no definite conclusion, but agreed with me that it was not a tuberculous process. The Wassermann was negative. The x-ray examination showed simply a much thickened pleura on the right, with the heart pushed over somewhat to the left. After studying this case for two weeks, Dr. Smith and I came to the conclusion that the process was either malignant disease or syphilis.

Nine months later, July 30, 1913, I saw him again. He had gained weight, and had more than held his own. His strength was distinctly better. He had been taking iodide of potash and mercury. On examination, I found very little air entering the right chest, but on the whole the condition in the lungs about the same as before except that there were fewer râles. I did not see him again until February 25, 1915. He told me that in December, 1913, he went to Saranac Lake after having had three months of pleurisy. He was tapped once and a little fluid removed. He stayed at Saranac Lake until March, 1915. During this time Dr. Sidney Blanchet tapped his chest once and removed one and a half pints of pus. His weight went down to less than 100 pounds. He raised much fluid pus by month. He was very sick in bed from December, 1913, to October, 1914, when he suddenly began to get better. He told me that he gained 21 pounds in 24 days. His present weight was 133 pounds which is more than he has weighed for many years.

On my examination at this time I found a normal temperature and pulse. The left side of his chest showed compensatory emphysema and no râles; the right side was dull above, flat below, much retracted, with only an occasional râle after cough. His general condition was excellent.

I am perfectly frank in stating that I do not know what pathological process has been going on in this man's chest. The impression I gathered from the doctors at Saranac Lake was that

they considered the whole thing to be tuberculosis. Despite their opinion, I am quite unwilling to believe this to be so. The length of time has ruled out malignant disease. Syphilis cannot be excluded. Extensive lung abscess or chronic empyema are the most probable diagnoses. No one, however, can be blamed in any way for calling this a case of pulmonary tuberculosis and treating it as such.

These cases have taught me several valuable lessons. Especially have I been impressed with the need of taking nothing for granted and not jumping at conclusions. From one examination alone, it would have been very easy to have called each one of these patients a consumptive. While this would have probably done no physical harm in any instance, and more likely the reverse, the injustice to the patient and to others is so manifest as not to need comment.

Again, this series has emphasized the multiplicity of chronic and subacute pulmonary infections and how little we know of the exact pathology of many of them. In these days, the words "tuberculosis" and "influenza" are used to cover much ignorance.

Finally, the value of a careful and painstaking history, and of a thorough routine examination of the lungs and of the whole body, not only once but often repeated, if necessary, has been clearly demonstrated.

III.

WHAT CONSTITUTES TUBERCULOSIS IN CHILDHOOD?*

By JOHN LOVETT MORSE, A.M., M.D., BOSTON,

I HAVE been asked to present a paper before you on what constitutes tuberculosis in childhood, presumably because it was thought that a pediatrician who does not make a specialty of tuberculosis might approach this subject, concerning which there is so much difference of opinion, with a more open mind than the specialists who have already preconceived ideas regarding it. I have found the subject a most difficult one, and make no claims that I have answered the question correctly. The title of my paper should be, therefore, "What I Think Constitutes Tuberculosis in Childhood." I am sure that not all of you will agree with my conclusions, but hope that they will find favor with at least a few.

It seems to me that in the first place it is absolutely necessary to distinguish between tuberculous infection and tuberculous disease. In this connection, infection may be defined as the state of being infected, and disease as an alteration in the state of the body or of some of its

organs, interrupting or disturbing the performance of the vital functions and causing symptoms of some sort.

For all practical purposes, the infant comes into the world free from tuberculosis. In round numbers, ten per cent. of all infants have become infected with tuberculosis by the end of the first year of life, and at 16 years not more than ten per cent. have escaped infection. A very small proportion of these children, however, have tuberculous disease. Those that are well and show no symptoms of tuberculous disease are little, if any, worse off than those who have not been infected. In fact, it is probable that in many, if not most, instances they are better off, in that they have established a certain immunity to tuberculosis.

Children infected with tuberculosis react positively to a von Pirquet tuberculin test, unless they are overwhelmed with the disease. A positive tuberculin test, in itself, signifies nothing more than tuberculous infection; it does not denote tuberculous disease. Taken in connection with other signs of disease, it strengthens, but does not prove, the assumption that the disease may be tuberculosis. The younger the child, the more strongly a positive von Pirquet test points towards a diseased condition being tuberculous. With certain limitations, a negative von Pirquet test excludes both tuberculous infection and tuberculous disease.

Tuberculous infection in childhood is almost invariably glandular. In the struggle to overcome the infection the glands become enlarged and indurated. When the cervical glands are enlarged they can be seen and felt. The mesenteric glands can be felt, if sufficiently enlarged, while the tracheo-bronchial glands, although neither visible nor palpable, give rise to certain definite physical signs. The demonstration of glandular enlargement, whatever its situation, even if other causes than tuberculosis for the enlargement can be excluded, does not, however, prove that the condition is one of tuberculous disease. It merely shows that there has been a tuberculous infection at some time. The condition is not one of disease unless other tissues are involved or the glandular enlargement is associated with symptoms of disease, such as fever, malaise, debility, loss of weight, and so on. This statement is quite as true as regards enlargement of the tracheo-bronchial as it is of enlargement of other glands, although there seems to be just now a tendency to consider the signs indicative of enlargement of these glands as evidences in themselves of tuberculous disease. This is especially true of d'Espine's sign.

There seems to be some difference of opinion: unfortunately, not only as to the significance of d'Espine's sign, but also as to what d'Espine's sign really is. This sign, as d'Espine originally described it, consisted in the persistence of the bronchial whisper below the seventh cervical spine. Others have claimed that the bronchial whisper is normally heard down through the

* Read before The Massachusetts Medical Society, June 8, 1915.

second dorsal spine, and some that it is heard even lower. Others have used the voice instead of the whisper, and still others have claimed to get the same results from the character of the respiratory murmur. My own belief is that the whisper is more reliable than the voice, and that the respiratory sound is less reliable than either. The respiratory sound gives fairly satisfactory results, however, and may be used in infants who will not talk or cry. It is also my belief that d'Espine was right in fixing the normal lower limit of the bronchial sound at the seventh cervical spine. I do not myself call the sign positive, however, unless the bronchial sound extends below the first dorsal spine. D'Espine's sign simply shows that there is some tissue denser than normal between the trachea and bronchi and the anterior surface of the vertebrae, which transmits the bronchial sound from the trachea and bronchi without modifying it. It shows nothing as to the nature of this tissue. Experience has shown that it is usually enlarged tracheo-bronchial glands. The etiology of enlargement of the tracheo-bronchial glands is the same as that of enlargement of other glands. Enlargement of the tracheo-bronchial glands, therefore, may or may not be tuberculous. If the enlargement develops in the course of some acute infection of the lungs or bronchi, it probably is not tuberculous, and usually promptly disappears. If it develops slowly and is persistent, it usually is tuberculous. A positive d'Espine sign, of itself, merely shows, therefore, that there is probably enlargement of the tracheo-bronchial glands. It shows nothing as to the nature or etiology of this enlargement. These points must be decided on other evidence. If a positive d'Espine sign is associated with a positive von Pirquet reaction, the chances that the enlargement of the tracheo-bronchial glands is tuberculous are increased. The chances of the enlargement being tuberculous are still further increased, if the sign is persistent. Even under these conditions, however, if the child is well, the condition should be looked upon simply as one of infection, not of disease. If a positive d'Espine's sign is not associated with a positive von Pirquet reaction, the enlargement of the glands is certainly not tuberculous, and it is of no significance in this connection. If a positive d'Espine's sign is associated with a positive von Pirquet reaction and there are signs of acute disease in the lungs, there is no way of determining at once whether the enlargement of the glands is tuberculous or not, and the presence of the signs shows nothing as to the character of the disease in the lungs. If there are evidences of tuberculosis elsewhere, the d'Espine sign is of no importance anyway. If a child has a positive d'Espine sign, a positive von Pirquet reaction, shows symptoms suggestive of tuberculous disease and no foci of tuberculosis are found elsewhere, it is probable that the enlargement of the glands is tuberculous, and that

they are not only infected, but also diseased, and the cause of the symptoms.

The significance of Roentgenographs which show a shadow in the location of the tracheo-bronchial glands is exactly the same as that of a positive d'Espine's sign, no more and no less. Great care should be taken, however, in interpreting the shadows in x-ray plates. Only the opinion of an expert is of much value, and that is not infrequently wrong.

There is very little room for difference of opinion as to the presence or absence of tuberculous disease of the cervical glands or bones. The same is true of tubercular peritonitis. The significance of enlarged abdominal glands is the same as that of enlargement of the tracheo-bronchial glands. The presence of physical signs of disease of the lungs is more likely to give rise to disagreement as to whether the condition is or is not tuberculous. A negative von Pirquet test, unless there is reason to suspect acute miliary tuberculosis, or the child is moribund, proves conclusively that the affection of the lungs is not tuberculosis, no matter what the x-ray findings, or whether d'Espine's sign is absent or present. A positive von Pirquet test does not, however, prove that the affection of the lungs is tuberculous. It merely increases the probability that it may be. The same is true of a positive d'Espine's sign and of Roentgenographs which show a shadow in the region of the tracheo-bronchial glands. A persistence or increase of the physical sign is in favor of the condition being tuberculous, but does not prove that it is, because influenzal and other infections of the lung are often of long duration. The persistence of constitutional symptoms and fever is of the same significance as the persistence of the physical signs. A positive diagnosis can be made in many instances, therefore, only after a lapse of considerable time or by the finding of tubercle bacilli in the sputum.

The greatest opportunity for difference of opinion as to whether a child has or has not tuberculous disease arises when a child showing a positive von Pirquet reaction manifests symptoms of general constitutional disturbance, such as fever, rapid pulse, loss of weight and strength, malnutrition, debility, fatigue from insufficient causes, anemia and dry cough, without any evident physical signs of disease. Every one will admit, of course, that this combination of symptoms and lack of physical signs when the von Pirquet test is negative does not indicate tuberculous disease. The significance of enlargement of the tracheo-bronchial and abdominal glands in this connection has already been discussed.

The presence of a definite history of exposure to tuberculosis, especially if prolonged, is strong evidence in favor of the view that the child has an active tuberculous focus somewhere, even if it is not discoverable, because of the well-known fact that a very large proportion of the children exposed to open tuberculosis in their homes be-

come infected. The younger the child and the longer the duration of the exposure, the more likely is the child to become infected and the more likely is the infection to lead to the disease. It must be remembered, on the other hand, however, that no matter how long or how great the exposure to infection has been, the child is not suffering from tuberculous disease unless it shows some manifestations of ill health. The history of the ingestion of the milk of tuberculous cows is of the same significance as that of exposure to human tuberculosis. A tuberculous family history, but without exposure, has the same sort of value, but much less, as a history of exposure.

Too much attention must not be attached in this connection to a slight elevation of temperature above what is ordinarily considered to be normal, that is, 98.6° F. I am sure that many children, apparently normal and certainly not infected with tuberculosis, frequently have a temperature between 99 and 99.5° F., especially if they have been playing hard or have been excited. A slight elevation of temperature is a very common thing from minor causes. In my experience it is much more likely to be due to some infection of the nasopharynx or the accessory sinuses, pyelitis or indigestion, than to tuberculosis. A little elevation of temperature, even if of considerable duration, does not, therefore, necessarily mean active tuberculosis, although it may.

Disturbances of nutrition, anemia, debility, fatigue and malaise are all symptoms of indigestion, overwork in school, over-exertion, late hours, lack of fresh air and many other things, as well as of tuberculous disease. Night sweats are unusual in tuberculous disease in childhood; they are not uncommon from other causes. A dry cough may be due to nasopharyngeal irritation, enlargement of the lingual tonsil and various other local irritations, as well as to tubercular tracheo-bronchial adenitis.

It is evident, therefore, that the presence of malnutrition, debility, slight elevation of temperature, anemia and so on, in the absence of evident physical signs of disease does not in itself justify a diagnosis of tuberculous disease, even if they are associated with a positive von Pirquet reaction. The presence of symptoms of constitutional disturbance without the physical signs of disease to account for them is suggestive of tuberculous disease,—that is all. Tuberculous disease should be considered seriously under these conditions, but it should not be taken for granted that it is the cause of the symptoms. Neither should it be taken for granted that it is not. When this combination of symptoms and lack of evident physical signs is present, the diagnosis should be made only after a careful and unprejudiced investigation and consideration of all the factors in the individual case. In this way only can errors in diagnosis be avoided.

There are many other points which might be

taken up and which are almost as worthy of consideration as those which have been discussed. What has been said, however, is sufficient, I think, to indicate what "I think constitutes tuberculosis in childhood," and what I conceive to be the difference between tuberculous infection and tuberculous disease.

DISCUSSION.

I. J. CLARKE, M.D., Haverhill: In the paper of Dr. Washburn, the 23 cases cited, autopsies by Dr. Ash, there were 8 of pneumonitis. I am taking this report as a basis for what I have to say. Regarding a condition which might be called pneumonitis I suppose that the location of it might easily contain some pus. It seems to me that a blood count in the absence of a high degree of mixed infection would show us a higher leucocyte count than ordinary, presuming that there is practically no fever, and it might show us a count high enough to suggest free pus. In the cases of septicemia, I think there were two, it is evident to me in the absence of marked evidence of mixed infection, or of physical signs in the lung, which would account for the condition, that a blood count might be of some help to us. In the cases of malignant disease—it appears to me that the marked displacement of the trachea is certainly a very unusual condition in an ordinary pleuritis. In regard to nephritis, it also seems to me that blood pressure perhaps ought to be taken more frequently. In this series of cases Dr. Ash did not report that they had any figures as to blood pressure. I think those four conditions,—pneumonitis, nephritis, septicemia and malignant disease,—constitute a very much larger percentage.

I believe that a great deal can be depended upon from the standpoint of the family history. In the records that I have taken, almost without exception you can find a history of exposure, of a definite, intimate, exposure, that is, all cases that in my opinion were tuberculous. The past history of the patient, it seems to me, is extremely important from the standpoint of attacks of what we call gripe, as to whether they were the symptoms of what might have been the lighting up of an old process.

There is also the evidence of the influenza bacillus, which I do not think, as a rule, is always looked after carefully. I also understand it is not an easy bacillus to find.

I should want to have a fever explained. It has been my custom to pass out to such parties as practical a thermometer, and require temperature taken three or four times a day for a month, whether I find fever at my first examination or not. It has been of great assistance in ascertaining definitely whether they had fever, and how much. I think also that a loss of weight should be accounted for. Until those two things are explained by some other reason we must assume, given a history of malaise, exposure, and general mean feeling, that the case is

tuberculous. In other words, it seems to me that it is a good deal more difficult to say to a patient that he has not tuberculosis than that he has. I think every physician has this experience,—that patients come to him and want to know if they have tuberculosis.

I should also want to know about the Wassermann test. That is not an easy matter for every one, especially in some of the small distant towns, but it seems to me that there is an occasional case of syphilis of the lung which clears up very quickly by proper treatment.

It is evident to me that there are certain heart cases which simulate tuberculosis. I feel that chest signs in any case must have some backing; a very distinct history of exposure, or something else to make you feel that they could be, or probably are, tuberculous. It appears to me also that we would occasionally find certain cases due to blood conditions. Either a borderline anemia, or a pernicious anemia, in which it would seem that a blood count would be important; also the appearance of the cells, as well as their varieties.

Another thing is the consideration of the conditions that are caused from the vocations where there is a good deal of dust. We know that the lung conditions oftentimes simulate tuberculosis. They have coughing, some sputum, which should be taken very carefully into consideration.

CARL C. MACCORISON, M.D., Superintendent North Reading State Sanatorium: I should like to ask Dr. Washburn if the 198 cases autopsied at Mattapan by Dr. Ash were taken at random, or were the doubtful cases only brought to autopsy. It would seem to me that an error in diagnosis of 11½% of all patients, dying in a hospital for the treatment of advanced consumptives, is rather high.

At North Reading about 75% of all admissions have been in the advanced stages of the disease. Last year we had 67 deaths; 65 died of pulmonary tuberculosis; all showed tubercle bacilli in their sputum during residence. One died of arterio-sclerosis, and one of organic heart disease.

I believe that about 84% of all admissions last year were found positive. On Monday of this week we had a census of 197 patients; 43 of that 197 have not been found positive. Six of the 43 are considered doubtful cases, and are under observation at the present time. Guinea-pigs have been inoculated with their sputum, and we are awaiting further developments. Four of these cases we believe to be organic heart disease, one unresolved pneumonia. We are very uncertain regarding the diagnosis of the sixth case. This leaves about 37 negative cases to account for. We feel that they are cases of pulmonary tuberculosis. Nineteen of them are classified as "advanced," 15 "moderately advanced," and 3 "incipient."

Now, out of the 37, 16 are hemorrhage cases; 8 were reported as having been found positive

previous to admission; 1 gives definite tubercular reaction; the remaining 12 give very striking histories; they have been exposed to the disease for a long period of time, and their subjective and objective symptoms are fairly well marked.

You must take into consideration that when we admit to our sanatoria a patient whose application is signed by a reputable physician, it necessitates the sanatorium physician using the utmost care before declaring a doubtful case not tubercular. We feel that we need from two to four months' study of a case before we can discharge it diagnosed as "not tubercular." The majority of the doubtful cases sent to us usually turn out to be valvular heart disease, although unresolved pneumonia, chronic emphysema, chronic bronchitis with bronchiectasis, and arterio-sclerosis account for frequent errors in diagnosis.

CHARLES E. PERRY, M.D., Superintendent Hampshire County Sanatorium: Hampshire County Sanatorium is, in spite of its name, a hospital for advanced cases, built under the act which requires cities to furnish local hospitals. We opened last September, and as yet the problem of making room for new cases has not been considered, for we still have plenty of beds. We have admitted since the hospital opened 47 cases. Of those 47 cases, 10 have shown no positive sputum during their sanatorium stay. Two of these non-positive cases have not been considered on account of their very short residence. One was discharged as probably non-tuberculous; 1 case of chronic bronchitis, with a history of syphilis, died with increasing complication. One other will probably soon be discharged as non-tuberculous. Two of these 10 cases were reported to have positive sputa within a year previous to their coming. There was another young man who was taken to the hospital, having previously been in a state sanatorium twice. He had an attack of asthma and lost about 15 pounds, and asked to be admitted. In about a week his condition improved so that there were no signs demonstrable except a slight dullness over the upper part of one lung. The remaining cases with negative sputa had fairly definite signs and the diagnoses were not questioned.

ALLEN G. RICE, M.D., Springfield: I do not feel that I can add anything to Dr. Hawes' paper. We make mistakes which I think perhaps we ought not to make if we took a little different attitude. From what I have gathered from Dr. Hawes' paper, it seems to me that if we paid, as he did, more attention to the history of these cases, personal and family, if we made sure when this patient was last perfectly well, how long he has been sick, how much weight he has lost, when he began to lose strength, if he has lost it markedly, we would have little points which, taken together, mean a great deal. It brings up the question of the relative value of the history

and the physical examination. It seems to me there can be no possible doubt. We have got to have the history; that is the most important.

The troubles with the stethoscope I think are two. In the first place the inability to appreciate signs, and in the next place the inability to interpret them. We make mistakes both ways. Simply because we find signs suggestive of tuberculosis does not mean that we should make the diagnosis. All the other points have to be taken into consideration. In other words, what we want to do is to regard the patient as a whole; not pay too much attention to the condition of his lungs. Where we have, as we do, many other chronic infections of the lungs besides tuberculosis, for instance, chronic influenza, chronic pneumococcus infection, malignant disease, and, in spite of the last speaker, I believe also syphilis, in devoting all our time simply to regarding the signs, we undoubtedly make a diagnosis of tuberculosis in cases where we should not. In addition to the history and the stethoscope we are also inclined to make mistakes because we pay too much attention to the so-called adjuncts to diagnosis. With adjuncts I include sputum examination. Sputum examination, I believe, is all right when we find tubercle bacilli. If we do not find them it does not mean the patient has not tuberculosis. The same thing can be said in regard to the x-ray. The x-ray shows lesions, but it does not necessarily show that the lesion is tuberculosis. I have seen plates where the x-ray man was perfectly positive that the case was tuberculosis, and on autopsy a few weeks later no signs of tuberculosis were found, but in this particular instance a well developed syphilitic process in the lung.

Another point which Dr. Hawes brought up was his general impression that the case was not tuberculosis; his general impression that the case was. I think these general impressions are valuable, even though they may not be scientific. One cannot get up and show why the case is or is not tuberculosis. At the same time I do believe that these general impressions are of value and should be given a certain amount of weight.

In addition to making mistakes in differential diagnosis we also make serious mistakes regarding the stage in which the disease exists. I believe tuberculosis is more often diagnosed correctly than is the stage of the disease, and the stage of the disease makes all the difference in the world to the patient. It has been said: What is the difference whether one makes an accurate diagnosis or not; treatment of chronic infections is in a great measure the same. It does make a lot of difference. In the first place it is impossible to give the patient any sort of prognosis without a correct diagnosis. The treatment is not always the same. Unfortunately, a certain stigma is attached to tuberculosis, which other chronic infections of the lung do not share. It is almost criminal to stamp a patient as tuberculous simply because he has a chronic process in his lungs. I am coming to believe that by

the time we find definite signs in the lung the case is beyond the incipient stage. These signs may be slight, may be localized at one or two points. At the same time when the signs are definite I cannot help but believe that in the majority of instances the case is beyond the incipient stage. In contradistinction to that, I also believe that a positive sputum examination does not mean that the case is necessarily beyond the incipient stage. There are bacilli in the sputum if the lesion is broken down. The lesion may break down in a very small area, so small that we cannot detect any signs over that area. Take also the cases of hemorrhage, especially a case with its first symptom,—hemorrhage, resulting from the breaking of some blood vessel. Simply because the patient has hemorrhage is no reason why we should regard that one sign alone and say the case is beyond the incipient stage.

Therefore it seems to me that the sooner we get away from paying too much attention to the lungs themselves, using our stethoscopes too much; and instead, regard the patient as a whole, treating him as a patient and not as someone with a diseased lung, we shall make fewer mistakes, and with fewer mistakes we shall do more to stamp out this disease.

FREDERICK T. LORD, M.D., Boston. It seems a hopeful sign that those who are especially devoting themselves to the study of pulmonary tuberculosis should be the ones who, as this meeting indicates, are calling our attention to pulmonary conditions simulating tuberculosis.

One of the most frequent difficulties is the differentiation of the more subacute or chronic types of the simpler infections from pulmonary tuberculosis. These two groups have in common such symptoms as cough and expectoration, with or without loss of weight, failing sense of well-being and elevation of temperature. There are, however, certain features of the history and physical examination upon which emphasis may be placed in distinguishing the tuberculous from the non-tuberculous cases.

The importance of the family history has been referred to by previous speakers. In this, greater importance should be attached to the opportunity for contagion than alone to a family history of the disease. Some evidence concerning the nature of the process may be afforded by a careful inquiry as to the evolution of the initial symptoms. A cough which begins as an infection in the upper parts of the respiratory tract, in the nose or the throat, and travels downward, is less likely to be of tuberculous origin than a cough, the initial symptoms of which are exclusively intrathoracic. There are, however, many exceptions to this, and we see a considerable number of patients with pulmonary tuberculosis with an initial acute upper-tract infection. In such instances it may be assumed that the milder infection has served to awake a slumbering tuberculous process.

Not all attacks of hemoptysis have an equal

bearing on the clinical diagnosis of tuberculosis. It is especially those attacks which are unpreceded by symptoms or signs of pulmonary or other disease which are to be regarded as of greatest importance in indicating a tuberculous origin.

A primary pleurisy, whether mild or severe, fibrinous or sero-fibrinous, almost invariably indicates that tuberculosis is the underlying condition. Intercostal neuralgia seldom, if ever, exists, and when this diagnosis is made it is usually a poor substitute for a confession of ignorance concerning the true nature of the process.

As regards the site of the disease, involvement of the apex is strong evidence for its tuberculous nature, but there are rare instances of apical invasion, even with cavity formation, which prove to be non-tuberculous at autopsy.

Valuable evidence against tuberculosis is furnished by negative examinations of the sputum for tubercle bacilli in cases in which there is an abundant and purulent sputum. Tubercle bacilli are frequently sought in vain in the early stages of pulmonary tuberculosis, when the expectoration is scanty and mucoid or muco-purulent, and these organisms may be demonstrated only after oftentimes repeated and careful search, but it is uncommon for the case to be one of pulmonary tuberculosis when tubercle bacilli cannot be found after repeated and diligent search in abundant and purulent specimens. The evidence against tuberculosis is still more convincing if at the same time the specimens are positive for elastic tissue and negative for tubercle bacilli.

A good deal has been said this afternoon with reference to chronic influenza. While it is true that infection with influenza bacilli can be demonstrated in a considerable number of patients with cough and expectoration, it seems to me a mistake to regard the presence of the influenza bacillus as an assurance against the tuberculous nature of the pulmonary process. It should be remembered that influenza bacilli are about as frequently present in the sputum of patients with, as in those without, pulmonary tuberculosis. It seems rather of academic interest than of practical importance to decide whether this case or that has influenza bacilli in the sputum. The most important question for decision is whether the patient suffers from tuberculosis or not. If not, then a number of other infections, singly or combined, may be responsible.

Regarding the use of tuberculin subcutaneously in the diagnosis of pulmonary tuberculosis, I have been very loath to use this test except as a last resort in diagnosis, and then only in strict accordance with Koch's original directions as to the way in which it should be used. It is best in adults to give an initial dose of 1/10 of a milligram, take the temperature every two hours for a period of two days, and if the patient fails to react, to follow this injection with successive doses of 1, 3, 5, and 7 or 10 milligrams, similar observations on the temperature being

made for an equal period between each injection. An initial dose of 10 milligrams may be followed by dangerous and even fatal consequences. Any one who has worked experimentally on tuberculous animals with tuberculin will appreciate that a large initial dose gives rise to a very severe local reaction, with marked hyperemia and edema about the site of the infection. I cannot believe that it is desirable to run the danger of inciting a tuberculous process to greater activity by the use of so large an initial dose as 10 milligrams, when a trivial reaction might have been obtained by the use of 1/10 milligram.

I am in agreement with those who believe that syphilis of the lungs in adults is one of the rarest of pulmonary diseases. I do believe, however, that syphilis of the respiratory organs is not so very uncommon in adults as an infection of the tracheo-bronchial region. It is desirable, therefore, if you have a case in which syphilis of the respiratory organs is under consideration, to make, if possible, a bronchoscopic examination to see if there is tracheo-bronchial ulceration, which may suggest the syphilitic nature of the process.

HERBERT C. CLAPP, M.D., Boston: One thing I particularly like in Dr. Hawes' paper is his cheerful admission that one can make mistakes in diagnosis without losing caste. Perhaps no one would boldly claim the opposite, but some, I am sorry to say, seem to give the impression, if not by word, yet by inference, that their dictum is final. Now we all make mistakes in diagnosis, and the only difference between us is as to the number we make. When I meet one of the religious sect professing "Holiness," and claiming that he has lived without committing sin for six months or a year or two, I instinctively thrust my hand into my pocket, and grasp my pocket-book (if there happens, by chance, to be anything in it). Similarly do I feel towards one of those men who is always cocksure in diagnosis. If a man with Dr. Hawes' skill and ability is so modest, why should not the rest of us be so, too?

He has very properly called our attention to the possibility of mistakes when we are dealing, or think we are, with advanced tuberculosis. We all agree, however, that the chance of making a mistake here is a hundred times less than it is when we have a possible early case of the disease. If a medical student or a physician of limited experience could draw an incorrect inference from this paper, he might perhaps think that the number of puzzling cases in advanced disease was greater than Dr. Hawes and some of the rest of us know it to be. I feel sure that in the vast majority of cases of advanced disease it is possible, with the modern means at hand, to make a correct diagnosis without unduly distressing ourselves. Now and then, however, as Dr. Hawes points out, we have an opportunity to exercise all of our discriminative faculties. The great tug of war, as we all admit, comes in the

prompt recognition of incipient tuberculosis. This, of course, is a much more practical question, and on the proper solution of it may depend the lives of innumerable people. On the contrary, in advanced disease the issues of life and death are not so sharply defined, and it is not so important for us to make a correct diagnosis. The only difference in some cases is that they die with the wrong label on. Medicine is a practical science, and when people employ us they have an eye more to results than to exact pathological conditions. This is not an argument for the neglect of careful study of advanced cases. But if our time is limited, it behooves us to spend more of it on early cases, where the results of our efforts may be at times simply marvelous, in contrast to those of thirty or forty years ago, than we do on cases most of which offer little or no hope. It is practicality versus scholasticism.

As to Dr. Hawes' Case No. 1, since he politely allows us to differ from his decision, it seems to me that there are fair grounds for considering this really a case of tuberculosis, largely because on one occasion the report of an experienced pathologist disclosed tubercle bacilli in the sputum. Since Koch's great discovery, announced in 1882, the world has been practically unanimous in considering the tubercle bacillus an incontestable proof of tuberculosis. If, in any given case I have thought otherwise of the diagnosis, on a positive report of a competent pathologist I at once throw up my hands and acknowledge the presence of the disease. At least, if the other evidences are not inconsistent, and they do not seem to be in this case, it is, of course, unnecessary to tell an audience like this that the healthy appearance of a patient, his refusal to die or to be severely sick, or to recover without leaving his work, are proof that he never had tuberculosis. The oft-quoted parable of the sower and the seed, showing that the bacillus flourishes in different individuals with a vigor largely proportionate to its pabulum, militates against this idea. Cases of later-proved undoubted tuberculosis are frequent, where many unsuccessful searches for the bacillus have both preceded and followed a positive finding, and we constantly admonish students of the vast difference in meaning between positive and negative evidence of this kind. Most boards of health caution even physicians against excluding tuberculosis, unless a considerable number of negatives are returned. To throw out this positive evidence of one in fifteen times, Dr. Hawes hints at the possible contamination of the specimen, or the carelessness or dishonesty of the examiner. It seems to me that in a large tuberculosis institution, where the principal reason for the employment of a bacteriologist is the examination of sputum, and where he is presumably honest and capable, such a contamination ought not to be allowed to occur. In the days of the early experimenters on animals with crude tuberculosis material, following Villemin's brilliant results in 1865, these

results were apparently for a time negated by careless contaminations. However, if they were excusable in those days, they are in these days of asepsis inexcusable. If contamination occurs now in one case, what is to prevent its occurring in many others? This admission, once made, would cast suspicion on the reliability of all sputum examinations. And to what point would that bring us? To my mind the microscopic examination in this case far outweighs the subcutaneous tuberculin test, which is supposed to be reliable only in from 80 to 90% of cases, and still less if the case is advanced. Even if non-tuberculous in 1914, couldn't this case have been tuberculous in 1904?

As to the cases of apical influenza simulating tuberculosis, while I admit their occasional occurrence, yet it seems to me that, from a thoroughly practical point of view, the discovery of this fact is likely to do the world at large more harm than good. Well do I remember in the early years of my practice the sweet morsel of comfort which physicians used to roll under their tongues by calling what now lung specialists would call fairly advanced pulmonary tuberculosis, merely cases of apical catarrh or bronchopneumonia. If we did that now, by how much greater would be the slaughter of the innocents?

I dread anything at the apex, and continue to dread it until I see both general and local improvement, whether I am sure of the exact pathological condition or not. If the physician is not worried by such a thing, why should the patient be worried? And after he has received the physician's dictum, what more natural than for the patient to neglect his trouble? Of the two evils, practically it is better to be even unduly alarmed. This does not mean that on the discovery of any apical condition, he should at once be hustled off to the sanatorium, but he should be watched for a while.

If the base of the lung is involved, and there is a differential diagnosis to be made between pulmonary tuberculosis and chronic pneumonia or influenza or carcinoma or sarcoma, primary or secondary, or syphilis or pleurisy, or the exceedingly rare affections, like actinomycosis, *e.g.* we have another problem. Without attempting to discuss the whole subject, which is a lengthy one, I will merely bring up one point which has been helpful to me.

Of course every physician knows that common pulmonary tuberculosis generally begins at one apex and works downwards, and later attacks the other apex, where it works also downwards, but at a respectful distance behind the first. Very few physicians, however, I imagine, have anything like an accurate idea of how universal this apical beginning is, and how rarely the disease begins at the base. By searching medical literature I never could find many satisfactory statistics on the subject; and so when I had a remarkably fine opportunity, about ten years ago, when I was connected with the State Sanatorium at Rutland, Mass., I decided to investi-

gate carefully the records of a large number of cases of pulmonary tuberculosis with this point in mind. Up to this time the examinations for admission to this institution, which aimed as far as possible at getting incipient cases, had been made entirely by lung specialists, mostly by Dr. Bowditch and myself, and by our assistants in the Sanatorium. With the valuable aid of my assistant, Dr. Lapham, who was then a resident in the Sanatorium, data were collected from 6769 cases, which showed that only about one in 500 could be called truly a basic case, that is, one which had not begun at the apex. We counted a few cases as apical which had apparently begun at the apex of the lower lobe. These results were to me somewhat surprising in going beyond the infrequency which I had previously suspected. They were published in one of our medical journals (*New England Medical Gazette* for August, 1905) and the facts therein contained were made the basis of an editorial in the *New York Medical Record* (August 26, 1905). This great rarity of basic tuberculosis without apical involvement, or with only secondary apical involvement, has been of service to me in the study of some of the problems presented by Dr. Hawes today.

WALTER C. BAILEY, M.D., Boston: Dr. Morse speaks with authority on any subject on which he elects to speak. The general tuberculosis question is difficult enough, but when we come to tuberculosis in children, with all the corollaries of that subject, we find the difficulties increasing.

There are just two points which I would speak of in connection with Dr. Morse's paper. He says: "In round numbers, 10% of all infants have become infected with tuberculosis by the end of the first year of life, and at 16 years not more than 10% have escaped infection. A very small proportion of these children, however, have tuberculous disease. Those that are well and show no symptoms of tuberculous disease are little, if any, worse off than those that have not been infected. In fact, it is probable that in many, if not most instances, they are better off in that they have established a certain immunity to tuberculosis."

That possibly may be true. At least that statement has been made by a great many people, but I believe it has been worked to death. I think it is time to turn over the page and look at the other side. Nobody knows what may happen to the tubercle bacillus when it is inspired by the child. We say that it gets into the gland and the gland protects the body from infection; but, nevertheless, the bacillus may be only sleeping when we believe it to be dead, and in reality is a constant menace.

The tubercle bacillus is a parasite of the human organism, and the interplay of forces is a very complex one, as shown by the formation of the tubercle which the body builds to hem in the bacillus. The fact that the body has accepted

the bacillus as a parasite is enough to startle us out of our equanimity and security, and to make us fear what we say is only an infection. I plead for the early diagnosis of infection, because we cannot tell how many of those infected will become actually diseased. All of us remember when those who specialized in tuberculosis were blamed for making a diagnosis of tuberculosis without the presence of the tubercle bacillus. Nowadays we criticize those who wait for demonstration of tubercle bacilli before making a diagnosis and instituting treatment. The same applies to children. If we wait for every sign in order to be sure, it will be too late. In that respect Dr. Morse says: "The demonstration of glandular enlargement, whatever its situation, even if other causes than tuberculosis for the enlargement can be excluded, does not, however, prove that the condition is one of tuberculous disease. It merely shows that there has been a tuberculous infection at some time. The condition is not one of disease unless other tissues are involved or the glandular enlargement is associated with symptoms of disease, such as fever, malaise, debility, loss of weight, and so on."

I personally, if it were my child, would rather have a diagnosis made, even though it was a wrong one, of suspected tuberculosis, so that proper treatment could be begun, than wait until that child has fever, malaise, debility and loss of weight. If physicians and parents can be trained to appreciate how widespread is childhood infection we shall have better care of children in the home and nothing but open-air schools. It is simply using common sense to give the children the best chance they can have to get rid of the infection and prevent the lighting up of the disease when they grow to young adult life.

You will see that my remarks point to the relation of childhood infection to adult pulmonary tuberculosis. That, of course, was not Dr. Morse's point of view, so I am not criticizing him adversely in his attitude.

Let us do something to increase this tentative diagnosis of infection, and by reporting it get figures and see what the true situation is. I believe this attitude to be most humane and intelligent.

FRITZ B. TALBOT, M.D., Boston: What Dr. Morse said in his paper is about what I feel about tuberculosis in childhood. I think that in discussing tuberculosis in childhood we forget that physiologically the child is not the same as the adult. When a person is once an adult he is always so, while the baby or infant is quite different. Infancy is the period of greatest growth and development, and may be characterized as a period of change; as the child nears adult life growth becomes less and physiological changes diminish.

Tuberculosis in the infant is primarily a disease of the glands, as Dr. Morse says. Tuberculosis in the adult is not a disease primarily of the glands, but of the organs. The disease has one

characteristic in the infant and another in the adult, and during childhood, the stage of transition, we have combinations of both types, depending on the age of the individual. For this reason a knowledge of the physiology and normal attributes of the infant is necessary to understand tuberculosis at all ages. My own personal opinion is that any positive skin tuberculin reaction in an infant under a year is not tuberculous infection, but tuberculous disease, and that nearly all of them die.

H. D. CHADWICK, M.D., Superintendent Westfield State Sanatorium: It is very unfortunate that we apply the term tuberculosis to a person in the last stages of disease and also to the child showing only bronchial gland infection. My assistant, Dr. Morgan, last fall went over the histories of about 150 children between the ages of 3 and 14 years. We recorded the symptoms of these patients as they were given to us, chiefly through correspondence. We sent the parents a blank on which certain questions were asked in regard to the onset of the disease and the symptoms which the child had had. In tabulating those symptoms interesting things have been brought out. In making a diagnosis of tuberculous disease it is necessary to consider three things,—symptoms, evidence of infection and physical signs. Of the symptoms tabulated in these 150 cases we found that the most frequent one was cough. That question was answered in 132 cases, and was positive in 99. The next in frequency was weakness: 70 of the group were said to have weakness; 62 had loss of appetite. I notice that Dr. Morse said night sweats were unusual in tuberculous disease in childhood. These answers do not bear out that statement. Out of 129 that replied to this question, 49 were reported to have had night sweats; 45 had shortness of breath and 44 had fever.

As Dr. Morse has said, cough does not mean tuberculosis, because it is caused by so many abnormal pharyngeal conditions, enlarged tonsils and adenoids, for example, that it is not a distinctive symptom. The next most prominent sign is weakness. To my mind that is the most important symptom in making a diagnosis of active tuberculosis, because it is usually present in a very early stage, both in adults and in children. Loss of appetite is evidence of toxemia, and, of course, tends to further the feeling of weakness. I recently made a statement which my friend, Dr. Hawes, took exception to,—that any child who had evidence of bronchial gland infection as made out by physical examination, and was unduly fatigued, showed marked weakness ("morning tire," as I expressed it) was probably infected with tuberculosis. There are very few children who are tired in the morning unless they have some toxemia. It is especially prominent in tuberculous infection. Children with an active tuberculous focus will have the desire to play, but not the requisite energy. The attempt to keep up with normal children makes

them tired and they show this strain by being nervous and irritable. Most of these children show interseapular dulness. Therefore, I think that a child who is unduly fatigued, has interseapular dulness, a positive von Pirquet test, and no other obvious cause, should be considered as having tuberculous disease and treated as such.

In regard to the mode of onset: These parents answered that in 38 cough was the first symptom; 22 of them answered that they were "run down," which is another term for weakness and loss of appetite; in 18 the diagnosis was made on physical examination of children in families where there had been an active case of pulmonary tuberculosis. In making routine examinations in the schools and in the families of patients where there have been fatal cases of tuberculosis, it is especially necessary to consider the distinction between infection and disease. Many of the children in whom a positive diagnosis was made had physical signs, but the characteristic symptoms were absent. They need not have been sent to a sanatorium if they had had a proper home in which to live. Of course that must be taken into consideration in prescribing suitable treatment. Are children to be sent away from home because they are only infected with tuberculosis? Not necessarily, because proper home care for those children is just as good as sanatorium treatment. But many of the children who go to dispensaries come from such poor homes that they cannot overcome their infection and would soon become active cases of disease if they were not sent away.

In considering the evidence of infection, the family history is most important. In 131 cases there were 86 with a positive family history. It is interesting to analyze that family history. We find that the diseased mother is the most dangerous member of the family as far as infection is concerned; a diseased father comes next; then in this series a diseased sister to other sisters, and a diseased brother to other brothers.

Of course we all realize the value of the von Pirquet test in children as indicating infection. The subcutaneous test I rarely use and only on adults. I think it is a hazardous thing to give a test dose of 5 or 10 mg. of tuberculin. I always begin with 1½ mg. and then increase, if no reaction, to 1, 3, 5, and 10 mg.

In this series of 145 children, the sputum was positive in 12%. That is a larger percentage than shown by those now in the Sanatorium. The patients who were admitted in the early period of our taking children at Westfield were more advanced. At the present time in a ward of 80 children under 12 years of age, only five have positive sputum.

Considering physical signs, we found in a series of 152 children that the weight of 104 was below normal, and were surprised to find that 48, or about one-third, were either normal, or above normal. We have a general impression that a child infected with tuberculosis is a puny,

pale, undersized child, but in 31% of these cases the reverse is true.

When we first began to examine these tuberculous children I felt that auscultation was quite important. The more examinations I do the more I depend on percussion. It is rather an unusual thing to find râles in children. One reason for that is that you cannot induce them to cough at the right time to bring them out. Percussion, on the other hand, is very important. Impaired resonance has the same relative value as an x-ray shadow or the d'Espine sign in indicating thickening of the lung or enlarged bronchial glands.

Several of the children sent to the sanatorium after the diagnosis has been made by x-ray examination, showed definite dulness between the scapulae. I cannot see where any additional evidence was obtained by the x-ray examination. Theoretically, impaired resonance should be brought out before a diseased area is dense enough to cause a shadow.

Percussion of children should be done with the patient standing, as changes in resonance can be elicited more clearly in that position. For this reason it is especially important whenever there is occasion to compare records of examinations made at intervals or by different physicians, that the patient be placed always in the same relative position, as otherwise the findings will vary greatly.

The D'Espine sign, I think, is of the same value, no more or less, than impaired resonance, and not so frequently found. The level at which the normal D'Espine sign is found varies more with the development than with the age of the child. A tall child will show a lower D'Espine sign than a short, chunky built child of the same age, and this fact must be taken into consideration.

One word about classification. As affecting prognosis, I think it is of minor importance in a given patient as to whether a case is called incipient, moderately advanced or advanced, as compared with the significance of the symptoms. The symptoms are the only measure we have of the resistance of the patient to the infecting organism. Upon that resistance depends the amount of arrest that can be obtained and the degree of future usefulness of the patient.

FRANCIS P. MCCARTHY, M.D., Boston: I had an opportunity while at Mattapan for two years of seeing cases clinically and also the post-mortem examinations. I might say here that life in a tuberculosis institution for advanced cases is not very exciting. You come across quite a few hundred cases of advanced tuberculosis in succession, and from a clinical standpoint, to examine every day a large series of advanced cases of tuberculosis is not particularly interesting. When we met an occasional non-tuberculous case at the hospital it was more or less of a treat to work over this case. It was my good fortune while at Mattapan to come across quite a series of non-tuberculous cases, which

made the service broader, not only to the resident physician, but also to the house officers. I might say that it is very difficult to make it interesting for the recent graduate from the medical school to come into a hospital for advanced tuberculosis and have him stay there for a period of six months. You must show him something besides tuberculosis. Fortunately, at Mattapan we were able to get an occasional case of non-tuberculous disease.

These non-tuberculous cases sent in as advanced tuberculosis were invariably picked up at the patient's home, referred by a private physician. They did not come through the out-patient department of the Consumptives' Hospital. Many of these cases were post-pneumonic cases, with signs in the chest, râles, dulness, etc.; others were cardiac cases with passive congestion. The physician seeing the case for the first time could not rule out tuberculosis, and makes a mistake in not following it up a little longer, as it only takes but a very few days to clear up those cases. The cancer cases are a little more difficult to diagnose except after more prolonged observation. When we meet a case of suspected carcinoma we hold it for closer study, and if possible get an autopsy to settle definitely the diagnosis.

The series of 23 non-tuberculous autopsies out of a total of 130 is rather high from a non-tuberculous standpoint, but this is explained possibly by the fact that we tried harder to get autopsies in those cases. We had one case of actinomycosis of the lung which was not diagnosed clinically, although we did rule out tuberculosis.

Syphilis of the lung is, to my mind, one of the rarest conditions known. Looking up the literature, it is very difficult to find any definite pathology on syphilis of the lung. In an institution like Long Island, where they have been handling tuberculosis and syphilis for years, they do not find cases of syphilis of the lung at autopsy. In a series of something like 3000 autopsies in Panama, held in the last ten years, there has not been one single case.

One speaker said it often takes two to four months to clear up a diagnosis as to the question of tuberculosis in a questionable case, in an institution. I heartily agree with him.

VINCENT Y. BOWDITCH, M.D., Boston: I want to make one or two remarks about the "basic processes" which Dr. Hawes has spoken of. They remind me of the cases which came to my attention as a student and in the early years of practice, just before the discovery of the tubercle bacillus. The name applied to such cases was often "anomalous tuberculosis," a term which I confess I never fully understood, although it implied something that differed from the usual forms of pulmonary tuberculosis, and was apt to be favorable in result. It was usually cited as something distinct from the apical forms. Whether these forms were of some other infection, like grippe, of course it would be impossible to say.

I note with great satisfaction, this afternoon, the conservative tone taken by the speakers, which is similar to that of the experts on x-ray in pulmonary disease. In all my recent conversations with those who stand pre-eminent in that department, I have noted that they often speak of "shadows which could not be said to be positively indicative of tuberculosis." I am led to speak of this from my own experience in cases where hasty conclusions have been drawn by those who are tyros in x-ray examinations. To cite a concrete example: A young lady came to me in great agitation because she had been told several weeks before by a physician that she had "shadows at the tops of her lungs," and that she probably had tuberculosis. She had not a single symptom of that disease other than a pain under the scapula which had troubled her for some time. On physical examination there was absolutely nothing to be found to confirm the diagnosis of tuberculosis. From the history I believed it to be one of those cases of pressure upon some intercostal nerve, and I sent her to Dr. Goldthwait, who in two weeks relieved her of the pain by means of a slight support on the chest. She was relieved immensely, both mentally and physically, and has never complained of anything since and has been perfectly well. I could give other instances of hasty diagnosis without sufficient clinical examination, but the one cited will serve to illustrate my point.

As to mistakes in diagnosis, we must all admit that we are neither omniscient nor infallible. I recall one case in the Sharon Sanatorium, where all the symptoms of the woman were those of a beginning apical tuberculosis: malaise, cough without much expectoration, with occasional slight hemoptysis, and even fever. We thought it was a case of incipient tuberculosis. After a time, her symptoms had a peculiar aspect. She suddenly began to show signs of marked dullness all over the right side of the chest. Great dyspnea came on, relieved only slightly by aspiration of bloody fluid, which made us change our diagnosis. She finally died suddenly of some cerebral trouble. Upon examination, we found malignant disease of the lung and pleura. All of her symptoms previously had been indicative of tubercular disease.

I agree with Dr. Hawes in regard to the great importance of close observation of patients in whom symptoms are of doubtful origin. Possibly I should differ somewhat from him as to the importance of sending them immediately to a sanatorium. I feel very strongly that if a person is in the class of life where he cannot look after himself as well at home, it is a great deal better to give him the benefit of the doubt and send him immediately to some sanatorium for observation. In my opinion, much less harm is likely to come from such procedure than from the possibility of losing valuable time should positive proof of the disease be found later.

SHRAPNEL BULLET IN BLADDER: REPORT OF A CASE.

By D. PEARCE PENNALLOW, M.D., BOSTON.

[From the American Women's War Hospital, Paignton, South Devon, England.]

THE more one sees of war-time surgery the more strongly is the fact impressed upon one that oftentimes bullets will do the most unexpected things as regards their course, and at the same time will do comparatively little damage.

The following case illustrates these points very well and is reported in the hope that it may be of interest.

W. R., aged 20, sapper, was wounded at Ypres on May 26, 1915, by a shrapnel bullet from a shell which burst about fifty yards from where he was standing. Following his being wounded he walked a distance of six hundred yards to the dressing station, where the wound was dressed, and then two hundred yards farther to the ambulance. In the ambulance he was taken to a general hospital and kept for four days; then sent to England, where he was admitted to my ward at the American Women's War Hospital on June 1, 1915, with the following history and examination:—

Well developed and nourished youth; able to walk without discomfort. Temperature and pulse normal. In median line of back at lower end of sacrum is a small penetrating wound $\frac{1}{2}$ in. in di-

FIG. 1.

Shows wound of entrance one-fourth inch in diameter surrounded by area of slightly inflamed tissue. Wound discharging very slight amount of sero-purulent material at time of entrance.

ameter (Fig. 1). About this wound is a small area which is somewhat reddened. No pain or tenderness on palpation or when he walks. No discharge from wound save very slight amount of sero-purulent exudate. No sinus made out. Patient feels perfectly well, but states that he has difficulty in urinating, especially when he stands erect. At such times the stream will start normally and will then be checked suddenly and this is associated with considerable pain. When he lies on his side he has no difficulty in urinating. He also states that when he

FIG. 1.
Anteroposterior view, patient lying on his back, showing shot and bullet just above and to the left of the symphysis pubis.

is lying down and turns over he can feel something moving about in his bladder.

For the first two days after being wounded, urine was slightly red in color and the first bowel movement was slightly streaked with blood, but there is now no macroscopic blood in urine or stools.

Rectal Examination reveals a firm sinus tract adherent to rectum, passing around to the left and then straight towards the bladder. No opening in rectum; no tenderness and no masses felt.

Urine Examination shows normal urine save for a slight amount of blood and pus.

Cystoscopic Examination shows a rounded mass lying just to one side of urethra. Mass moves when patient turns. Wound in bladder wall not made out.

Stone searcher passed into bladder shows the presence of a metallic foreign body.

X-ray Examination taken in different planes shows a foreign body in bladder region. (Figs. 2 and 3.)

June 29, 1915, ether and operation. Suprapubic cystotomy. Bladder opened through a small incision and bullet located and removed by bullet forceps. Wound in bladder closed tightly. Small drain to prevesical space. Constant drainage.

The foreign body removed was a lead ball $\frac{1}{2}$ in. in diameter, and at time of removal was becoming encrusted in several places with salts.

Following the operation patient had an uneventful convalescence and the wound was entirely healed in two weeks. Since that time patient has felt well; he can pass urine without any further trouble and will soon be able to return again to duty.

REPORT ON OBSTETRICS.

By ROBERT L. DE NORMANDIE, M.D., BOSTON,

AND

JOHN B. SWIFT, JR., M.D., BOSTON.

CONTENTS.

CAESAREAN SECTION IN BREECH PRESENTATIONS.—RUPTURE OF A CAESAREAN SCAR.—BREAST FEEDING.—ANALYSIS OF 679 CASES OF ABORTION.—SERUM STUDIES IN PREGNANCY.—EFFECT OF PUBOTOMY UPON THE COURSE OF SUBSEQUENT LABORS.—NITROUS OXID ANALGESIA IN OBSTETRICS.

CAESAREAN SECTION IN BREECH PRESENTATION.

THREE papers have recently appeared where the authors favored Caesarean section in primiparous breech presentation.

Shearer¹ reviews the possible causes of breech presentations and suggests that one cause has not previously been noted. He thinks that when long cords are present and become wound about the neck, making a relatively short cord, the normal influence of gravity which causes a head presentation is overcome with the resulting breech presentation. He suggests a Caesarean section in deformities of the pelvis

and when large babies occur, but he does not come out strongly for Caesarean section in all primiparous breech cases.

Williams,² on the other hand, believes that because of a probable fetal mortality of from ten to thirty per cent., combined with severe injuries to the maternal soft parts an elective Caesarean section in primiparous breech cases should be performed.

Bowen³ reports a Caesarean section in a primiparous breech. The patient was forty years old and he allowed her to go in labor for twenty hours with no appreciable progress and then performed a Caesarean section. He obtained a living baby and the mother made an excellent convalescence.

Williams reports two cases where he did a Caesarean for a primiparous breech. They were both elective Caesareans, one made a normal convalescence and the other had a low grade uterine sepsis but eventually made a good recovery.

Williams says that when a breech occurs in a primipara the cause is either a disproportion between the fetal head and the pelvic brim or a disproportion between the fetus and the shape or size of the uterus. That these causes, one or both, may be present in a breech presentation cannot be denied, neither can it be proved that these two causes are the only reasons for a breech presentation. Shearer's suggestion of the coiling of the cord about the neck may prove to be a cause. That these causes that Williams suggests are not always present must be admitted, for all physicians have seen cases where there was no disproportion and the patient has successfully been delivered of a living child.

These three papers show the trend of modern obstetrics, the widening of the indications for performing Caesarean section, but in connection with the following abstract it is clear that Caesarean section is not to be advised lightly and as a very simple procedure.

RUPTURE OF PREGNANT UTERUS THROUGH THE SCAR OF A FORMER CAESAREAN SECTION.

Walls⁴ reports two cases where rupture of the pregnant uterus took place through the scar of a former Caesarean. The first case was seven months advanced in her fourth pregnancy, having had three previously successful Caesarean sections. Laparotomy was done, but the patient did not rally.

The second case was in a patient within ten days of term of her second pregnancy. Signs of accidental bleeding occurred. Walls opened the abdomen and found the previous Caesarean scar was wide and very thin, with blood oozing from the lower end. A dead baby was removed through the incision and a supravaginal hysterectomy done. The patient made a good recovery.

Shaw⁵ reports the third rupture. The patient

was within a week of full term in her second pregnancy when she was seized with a sudden sharp, very severe abdominal pain while in bed and asleep. Within a few hours the abdomen was opened and it was found that the whole of the previous scar had opened up. The dead child was delivered and the uterus removed by supravaginal hysterectomy.

BREAST FEEDING.

Waller,⁵ in an excellent article on breast feeding brings out many interesting points in the physiology of the breast. He feels that it is the lack of accurate knowledge on the subject of lactation that has given bottle feeding its chief impetus.

Waller divides his article into three parts: (1) the periodicity in the secretion of the milk, (2) the size of the meals, and (3) the infant's appetite.

Waller feels that the periodicity of the secretion of the milk is most important and that the inability to nurse is due in a large measure to a failure to observe this characteristic. In primiparae Waller says it is not always easy to demonstrate this periodicity until nursing has gone on three or four weeks, but in multiparae it appears much earlier. This periodicity is established by the regular stimulation of suckling with a sufficient interval between the infant's meals. The mother becomes aware of a sensation in the breasts which is variously described as a rushing, tearing or painful stabbing, known as the "draught," and it is experienced as soon as the child's mouth is applied to the nipple. Waller feels that the maintenance of this so-called "draught" is, perhaps, the surest sign that breast feeding has been normally carried out, and that when the converse is present, suspicion should be roused that the nursing regime is not satisfactory.

Too frequent suckling is the commonest cause of failure of nursing. Waller says that the only basis for the prevalence of so unexceptionally bad teaching is the anatomical view that the stomach of a newborn child is so small that it needs frequent refilling. Because of this too frequent nursing the infant becomes restless and dissatisfied, cries at the breast and even refuses to suckle, with the weight remaining stationary. The result is that supplementary feedings are begun, and comparative peace following, the parents are at once convinced that the milk supply was insufficient.

Waller shows charts in his article to bear out this contention that on fewer nursings infants gain better. He shows from tables that the total amount of milk obtained increases as the number of meals diminishes. With the increasing of the interval Waller admits that the meals obtained become far larger than is compatible with the view usually held about the gastric capacity. But he also shows that babies nursed as above outlined have no objection to waiting

many hours for their food, show no signs of digestive disturbances, gain weight rapidly and develop strongly. From these facts Waller believes six meals are better than ten and that when the infant is six or eight weeks old five or four will be sufficient.

ANALYSIS OF 679 CASES OF ABORTION.

Lackner⁶ analyzes 679 cases of abortion which occurred during the period from January, 1909, to January, 1913, at the Michael Reese Hospital in Chicago. These cases included all types of abortion. The causes of these abortions were difficult in many cases to determine. In 100 consecutive cases the Wassermann test was done, and only in four cases was the reaction positive. Lackner's findings in this respect corresponded closely to Trinchese's, who says that syphilis plays practically no rôle in abortions during the first four months of pregnancy.

There were four deaths in the series of 679 cases, or a percentage of 0.06. Of these four cases one was treated conservatively and three actively, but all were brought to the hospital moribund.

The treatment as carried out in these cases was as follows: In threatening abortion with less than one finger dilatation and only slight bleeding, absolute rest in bed. No vaginal examination except the first one and no brisk catharsis. Fifteen to twenty grains of sodium bromide were given four to six times a day. A hypodermic of morphine sulphate grains 1/4 and atropine sulphate grains 1/150 was given (whether this was repeated is not stated in the article). These patients were kept in bed two weeks and then sent home, but as many of these patients came from the very poor laboring class they returned in a few weeks with a diagnosis of incomplete or inevitable abortion. (It has been our custom in such cases to empty the uterus, for it has been conclusively shown that with women of this class it is impossible for them to have the rest which is necessary in order that they may go to a successful issue. This series of cases again demonstrates the advisability of our course.)

The preparation of the patient was as follows: the external genitals were shaved and scrubbed. The vagina was cleansed with green soap and water and irrigated with 1:5000 bichloride of mercury solution. A tent was then inserted and a cotton pledget was placed posteriorly, laterally and anteriorly to the cervix to keep the tent in position. Tents were kept in the uterine cavity twenty-four to thirty-six hours and no complications followed their use. After the cervix had been dilated sufficiently a finger curettage was done. The forefinger of one hand was placed in the uterus and the other hand grasped the uterus through the abdominal wall and guided it over the finger within the uterus. The side of the finger rather than the tip was used to free the placental tissue, which

was removed by the placental forceps. The dull curette was used only when the placental tissue could not be freed digitally. The cavity of the uterus when empty was irrigated with $\frac{1}{2}\%$ iodine solution. The patient was kept elevated in bed for three days and given fifteen drops of ergot and hydrastis three times a day for two days. Bowels moved by daily enema. If there were no complications the patient was allowed to get out of bed on the fourth day.

Smears and cultures, both anaerobic and aerobic, were taken in fifty consecutive cases, but they showed no constant findings and are not of great value. The article ends with twenty-eight references to the subject under discussion.

SERUM STUDIES IN PREGNANCY.

The authors,⁷ considering that the mobilization of proteolytic ferments has been proved to occur during pregnancy, undertook an investigation to determine first, if extracts of placenta injected intracutaneously or applied to the abraded skin of pregnant women would be followed by the train of phenomena generally recognized as a local anaphylactic or allergic reaction and ascribed to the action of a proteotoxin; and second, if such a reaction occurs, whether it is due to a specific or general ferment and under what circumstances it would occur.

They review the question of the relation of anaphylaxis to labor as studied experimentally first by Sauerbruch and Heyde, and later by a further series of investigators. A thorough description of the preparation of their extracts is given, the placental extract being given the name placentin, and a control extract made from beef kidney and from human male and female kidneys called nephrin. They found it necessary to change the method of preparing the extracts a number of times, due to the fact that they were getting local reactions from the solutions which they used to carry the extracts. Their experiments are carefully detailed, and at the end of the article they discuss their findings as follows:—

"Without at this time entering upon a general discussion of the mechanism of anaphylaxis and the nature of the substrat in anaphylatoxin production or the action of the ferments in the serum of pregnancy in this process, the results of this study indicate that during pregnancy there is an increase of a general proteolytic ferment rather than a production of a ferment specific for placental protein alone. Whether this increased tryptic power of the serum in pregnancy is due to a simple increase of normal tryptic ferment or to the production of new proteolytic and amboceptor-like bodies of a general nature capable of attacking not only the proteids of placental, but of other bodies as well, is being studied and will be reported upon in a subsequent communication. At present it may be stated that these ferments have several of the characters of amboceptors, and their lack

of specificity is comparable to the lack of specificity of the cytotoxins in general.

"While we have naturally hesitated to report upon these local skin reactions in pregnant and puerperal women until a relatively large number was studied, in view of the contradictory results obtained by others, we feel justified in concluding that the reactions were anaphylactic in nature and due to an anaphylotoxin produced by the action of general ferments upon a protein substrat.

"We have not been primarily interested in the question of the practical diagnostic value of a skin test for pregnancy, and have merely recorded the results as observed. We do not believe at present that this reaction possesses a practical value in diagnosis, certainly not among women who have borne children."

SERUM STUDIES IN PREGNANCY. II. A STUDY OF THE SPECIFICITY OF THE FERMENTS IN PREGNANCY AND THE MECHANISM OF THE ABDERHALDEN REACTION.

The objects of this investigation as undertaken by the authors,⁸ were as follows:—

First, to determine by means of intracutaneous and intravenous injections of the material if proteotoxins are produced during the Abderhalden reaction. Second, to study the specificity of the ferments in pregnancy by the same method. Third, to study the mechanism of the reaction, and particularly the source of the protein matrix. Fourth, to study the relation of a complement to the proteolytic ferments of pregnancy.

As in the first article, the authors give a very careful and comprehensive description of their technique, both in the preparation of the various sera and their methods of using. Both animal and human experiments were made. The authors' discussion of their experiments is as follows:—

"According to their experiments pregnancy serum contains proteolytic ferments which, when rendered active (*in vitro*) produced toxic substances capable of increasing the local and general reaction analogous to those observed by Vaughan, Friedberger and others and regarded as anaphylactic in nature. These observations support the views expressed in our previous communications concerning the probably anaphylactic nature of the reaction following the intracutaneous reaction of placentin and nephrin, although these occurred to some extent in non-pregnant women and in men and in this matter lacked absolute specificity. It is highly probable that the process of proteotoxin formation in the skin (*in vivo*) is identical with that occurring in the test tubes (*in vitro*.)

"Our experiments also suggest that in pregnancy serum there are two sets of proteolytic ferments, one composed of normal non-specific ferments and the second of a more or less specific ferment. While the latter may not be

specific in the sense of absolute digestive power for placental proteid alone, yet it appears to be rendered active in the presence of placental tissue to a much lesser extent, or not at all, by other human tissues and those of lower animals, and practically not at all by inorganic substances.

"Our experiments, however, show that inorganic substances, as kaolin, are capable of releasing the normal tryptic activity of a serum, probably through the absorption of anti-ferment, followed by the digestion of serum protein. Our work indicates that this action is non-specific and the result of the release of normal proteolytic ferments, whereas the activity of the specific ferments in pregnancy serum is best in evidence in the presence of placental tissue.

"It is probable, therefore, that the Abderhalden reaction is an anaphylactic reaction (*in vitro*) in so far as its mechanism is concerned, for the reason that normal human sera contain variable amounts of proteolytic ferments. It is reasonable to expect that the intracutaneous injection of protein material into the skin may in a small percentage of persons be followed by a local reaction due to non-specific proteotoxin production.

"In view, however, of the high specificity of anaphylactic reaction one cannot explain the mechanism of anaphylaxis and production of anaphylatoxin upon simple absorption of anti-ferments alone, without the assumption at least that the specific anti-bodies or ferments are produced after the parenteral introduction of proteins and that these are released through absorption of the anti-ferments by means of the specific protein antigen alone.

"With the Abderhalden reaction as now conducted it seems impossible to avoid a certain percentage of non-specific reactions due to the presence of non-specific proteolytic ferments. A means of removing these preliminary to the main test for specific ferments will probably render the reaction more specific within wider quantitative limits.

"While numerous investigations indicate that the protein matrix is the serum protein itself, we cannot at present subscribe to this view and exclude the tissue substrat entirely as a second matrix; rather, we are still inclined to believe that, in addition to digestion of serum protein, the tissue substratum is likewise attacked and adds to the production of proteotoxic substance."

THE EFFECT OF PUBIOTOMY UPON THE COURSE OF SUBSEQUENT LABORS.

Williams⁹ reports a series of forty-three pubiotomies upon forty women without a maternal death. With one exception he used the semi-subcutaneous method of Doederlein, and the operation has not been resorted to until a prolonged test of the second stage has demonstrated the impossibility of spontaneous deliv-

ery. The operation has been immediately followed by the delivery of the child. The operation has been restricted to patients presenting moderate degrees of contraction, the smallest pelvis having a conjugata vera of 7 cm. One-half of the cases had vaginal tears which communicated with the pubiotomy wound. No complications occurred, and Williams does not regard them as any more serious than ordinary perineal tears, if repaired at once. The bladder was injured twice and was immediately repaired, one case healing readily and the other requiring subsequent repair. The after-care is very simple, according to Williams. He expects and hopes for fibrous union between the cut ends of the bone. Consequently no attempt at immobilization of the pelvis is made, a simple four-inch strip of adhesive plaster encircles the pelvis at the level of the trochanters and the patient is placed on a Bradford frame. Injury to the sacro-iliac joint can always be prevented if the conjugata vera does not fall below 7 cm. and if the cut ends of the bone are not allowed to gape more than 5 cm. during delivery. The patients usually begin to walk early in the third week and are discharged one week later. All of his patients within a few months were walking and working as well as before, with one exception,—a woman who had suffered from relaxation of the sacro-iliac joint before the operation. All of the bone wounds, with one doubtful exception, healed by fibrous union, and a definite excursion of the two ends of the pubic bone can be felt with every step. This has in no way interfered with locomotion and has caused no pain. Twenty of the forty women have subsequently been delivered and have had twenty-seven full term and three premature deliveries. Williams states that following pubiotomy the increase in the size of the pelvis occurs more often in the transverse diameter of the outlet than in the conjugata vera. Six cases showed an enlargement of the conjugata vera, but in two only did it amount to so much as one cm. Eleven cases showed an increase in the transverse diameter of the outlet varying from one to three cm. Four cases showed a radical change in the pelvis as a result of the operation. A simple flat pelvis, a generally contracted pelvis, and a typical funnel pelvis became normal, and a generally contracted funnel pelvis was converted into a simple justo-minor one. Two other cases that have not been delivered again also show a marked change in their type of pelvis. Williams regards these observations as of the greatest importance.

Out of this series twelve women had one, six women had two, and two women three labors after the initial pubiotomy. Considered in another way, ten women had twelve spontaneous labors, while the other ten had eighteen labors which ended as follows: eleven Caesarean sections, three repeated pubiotomies, one spontaneous full term, and three premature labors. Four children were lost out of the twenty orig-

inal pubiotomies, but of the thirty subsequent children all but the premature ones were discharged from the hospital well. Williams believes that of the ten women who had spontaneous labors afterwards the pelves of eight were affected by the original pubiotomy.

In the second series of ten women with eighteen subsequent labors there was no evidence that any permanent benefit followed pubiotomy. None of the pelves became larger nor were the ensuing labors any easier. Only one of the fourteen full-term children was born spontaneously while the rest were delivered by Caesarean section or repeated pubiotomy. In Williams' series primary pubiotomy was done upon eleven primiparae and nine multiparae, who had eighteen and twelve subsequent labors respectively. The primiparae had four spontaneous and eleven operative labors, as compared with nine spontaneous and three operative labors, respectively, in the multiparae. Apparently this discrepancy was entirely in favor of the multiparous women.

Williams has learned that in labor complicated by a funnel pelvis pubiotomy is an ideal operation and in young women is preferable to any other procedure. He permits each patient to go into labor, and when it has come to a standstill he applies the Gigli saw prophylactically before applying forceps. This has two advantages: first, it prevents too powerful traction on the head to demonstrate that delivery by forceps is impossible; and second, it tends towards greater conservatism by preventing the performance of primary pubiotomy solely upon indications furnished by pelvimetry. In the funnel shaped type of pelvis in young primiparae, Williams believes that pubiotomy is greatly superior to Caesarean section, since no matter how successful the latter may be it only relieves the immediate difficulty and must be repeated in each subsequent labor, whereas pubiotomy may permit spontaneous labors later. Williams, however, believes that in elderly primiparae and in multiparae with previous disastrous obstetrical experience an elective Caesarean section is the better operation. In considering the indications for the operations, Williams divides the patients into four classes, according to the time and the condition in which they come into the hands of the obstetrician, assuming that the labor is complicated by moderate degrees of pelvic contraction: (a) Patients under observation during pregnancy or at the onset of labor. (b) Patients admitted late in labor, but who are otherwise in good condition. (c) Patients admitted late in labor who have already been subjected to attempt at delivery or who are exhausted or infected. (d) Patients admitted late in labor with child already dead. With the first type of case, if there is considerable doubt in the mind of the operator as to the advisability of Caesarean section Williams believes that the patients should be allowed to go in labor, and be given a test of several hours in the second

stage. Usually the child is born spontaneously, but occasionally the expected engagement and descent failed to occur. Here, in place of a late Caesarean section, Williams would resort to pubiotomy, as its mortality at this time is minimal and the chances for the child are excellent. In this class of cases he states that pubiotomy is a makeshift operation which has become necessitated and justified by an error in prognosis. He does not believe that early Caesarean section and pubiotomy are competitive operations, but he does believe that a number of patients may be saved Caesarean section if the possibility of pubiotomy is remembered if their labor does not progress as it should. The same argument holds good in his second class of case. The third type of case offers the greatest possibility for errors of judgment. Conservative Caesarean section is too dangerous to be seriously considered. The choice lies between Caesarean section followed by hysterectomy, or pubiotomy. If Williams feels reasonably sure that the patient has not been infected, pubiotomy is done and the child-bearing function preserved. On the other hand, if there is a strong suspicion of sepsis either craniotomy or Caesarean section followed by hysterectomy is chosen, depending somewhat on the patient's age. In the last type of case craniotomy is the only operation indicated.

Williams' conclusions are as follows:—

(1) In somewhat more than one-third of our cases, particularly the funnel pelves, pubiotomy has resulted in sufficient enlargement of the pelvis to permit subsequent spontaneous labor.

(2) My experience has taught me greater conservatism in the employment of pubiotomy which should not be regarded as an elective operation, except in funnel pelves in young women.

(3) In contractions of the superior strait, our ideal should be to differentiate the patients into those requiring Caesarean section at the onset of labor, and those in whom a spontaneous outcome may reasonably be expected. Pubiotomy should be employed in the latter only when failure of the head to engage after a prolonged second stage has demonstrated that the prognosis was erroneous.

(4) Pubiotomy does not compete with elective Caesarean section at the onset of labor, but is far safer than conservative Caesarean section late in the second stage.

(5) In moderate degrees of contraction of the pelvic inlet the great field for pubiotomy is in patients who have not been seen until late in labor, or who have been examined by those whose technic is questionable. In such circumstances, conservative Caesarean section is too dangerous, so that the choice lies between pubiotomy, Caesarean section followed by removal of the uterus, or craniotomy upon the living child. If definite infection is present, pubiotomy is contraindicated.

(6) In version or breech extraction where there is moderate disproportion, prophylactic laying of the Gigli saw adds greatly to the

peace of mind of the operator, as it enables him to resort promptly to pubiotomy if unexpected difficulty is encountered.

(7) The most promising field for pubiotomy is in funnel pelvis in young women, as it not only permits the delivery of a living child, but offers a reasonable prospect of permanently enlarging the pelvis so that subsequent labors will end spontaneously.

NITROUS OXID GAS ANALGESIA IN OBSTETRICS.

The use of nitrous oxid gas combined with oxygen in order to produce analgesia in obstetrics is not a new procedure. Webster¹⁰ of Chicago was one of the first here in America to try it out and to report favorably on its use. He first began using it some ten years ago in certain chosen cases, at first for operative work. In 1909 he performed an abdominal Caesarean section under gas and oxygen. During the past year in the maternity service at the Presbyterian Hospital he began the use of nitrous oxid in labor to abolish the pains caused by the contractions. He believes the method is a complete success. Usually the administration of the gas is begun when the patient complains of second stage pains, though it may also be used during the first stage. Webster uses a small nasal inhaler, the mouth of the patient being uncovered. Light inhalation generally suffices to produce the analgesic effect. It is not necessary to cause asphyxiation or jactitation. Webster uses pure nitrous oxid gas or gas with oxygen.

Lynch¹¹ reports its use in 34 cases more than one hour, 32 cases more than three hours, four cases more than four hours, and in one case more than six hours.

Webster and Lynch and the other writers all agree that with the portable machines that are now present on the market gas can be used at homes as well as at hospitals.

Davis¹² recommends a more complicated machine, having an automatic regulator by which means a constant pressure is maintained in the gas bag. Davis says the cost of using this method of analgesia is about \$1.50 per hour.

Davis says he starts the gas whenever the uterine contractions become painful, and if it is early in labor he uses a higher per cent. of oxygen and gives three or four inhalations; later less oxygen is given and five or six inhalations are allowed.

Webster, Lynch and Davis all feel that the analgesia does not lengthen labor, but rather will shorten it, that there are no ill effects to mother or child, and that the strength of the uterine contractions, no matter how long the gas is given, is not diminished. Skeel¹³ agrees with the above and adds that there is no danger of postpartum hemorrhage. Luther¹⁴ reports that he has given gas in fifty-four cases and gives the history more or less detailed of seven of the cases. Among these seven cases are high forceps, normal deliveries, and one case when for-

ceps failed and pubiotomy was done. In this last case analgesia was continued for five hours and then complete anesthesia for two hours and forty minutes. One hour after the delivery was accomplished the patient was eating breakfast.

Luther speaks, in cases where the baby, for some reason, does not cry at once, of blowing out the baby with oxygen by giving straight oxygen to the mother.

Heaney¹⁵ advises the use of oxygen for he thinks the analgesia is more readily maintained and that the headaches which sometimes appear are then more infrequent. He warns us that the amount of gas necessary varies with the individual susceptibility and that if the mixture is too rich the analgesia is imperfect, the patient becomes cyanotic and the consciousness is clouded.

Book Reviews.

X-Rays: How to Produce and Interpret Them.

By HAROLD MOWAT, M.D., Edinburgh, Temporary Lieutenant, R.A.M.C. London: Henry Frowde and Hodder and Stoughton. 1915.

This volume in the series of Oxford Medical Publications is intended as an elementary manual on the subject of the production of the Roentgen ray and the clinical interpretation of the plates obtained by its use. The subject of therapeutics is not considered, but emphasis is laid upon diagnosis. The book is divided into two parts, dealing respectively with production and interpretation; and the second part is di-

vided into five chapters dealing respectively with the thorax, the alimentary tract, the genito-urinary tract, injuries of the bones and joints and diseases of the bones and joints. The work is admirably illustrated with 106 figures, of which twenty-five represent apparatus and the remainder are actual skiagrams of various parts of the body. The volume should be of especial value to practitioners who wish to acquire an understanding of the principles of x-ray production and of its diagnostic employment in practice.

The Early Diagnosis of Heart Failure and Other Essays of the Heart and Circulation. By T. STACEY WILSON, M.D. (Edin.) New York: William Wood and Company. 1915.

The book represents a collection of different essays dealing mainly with heart failure. These essays were written at different times, which somewhat disturbs the balance of the book. The author in many senses can be regarded as a special pleader for certain signs and terms that seem strange to us. For example, he lays great stress upon the value of an abnormal rise in the average level of the diaphragm as a guide to the volume of blood in active circulation. He also discusses at great length distensibility of the heart. He uses many of the ordinary terms of medicine to mean quite otherwise than the accepted meaning. There are practically no references to the literature and little mention is made of pathology. The book does represent, however, the wide clinical experience of a careful, thoughtful observer who embraces the opportunity to present some unusual ideas.

Diarrheal, Inflammatory, Obstructive and Parasitic Diseases of the Gastro-Intestinal Tract. By SAMUEL G. GANT, M.D. Philadelphia: W. B. Saunders Company. 1915.

The underlying facts of diarrhea are very little understood by the medical profession. Dr. Gant has made a noteworthy attempt to bring a certain amount of order out of the chaos of conflicting evidence. The author has arranged his material well. The discussion is adequate and concise. He takes up the surgical treatment in a thorough yet conservative fashion. There are special chapters on tropical and parasitic diseases. All in all, the book can be recommended as a much needed, lucid exposition of a confused subject.

Consumption. By JOHN B. HAWES, 2d, M.D. Boston: Small, Maynard and Company. 1915.

This is one of a considerable number of books called the "Welfare Series." Dr. Hawes is peculiarly well fitted to contribute the volume on consumption. The book is not designed for

the expert in tuberculosis, but for the busy general practitioner and the laity. Dr. Hawes writes with vigor and enthusiasm and withal paints an honest and accurate picture of the fundamental facts about tuberculosis, its diagnosis and treatment. The author indulges in no glittering generalities, but answers in a sane practical way the multitude of questions that consumptive patients really ask. It is a cheerful message that Dr. Hawes bears and it will help many doctors and patients who read it.

The Medical Annual; A Year Book of Treatment and Practitioner's Index. Bristol: John Wright and Sons. 1915.

This exceptionally belated thirty-third annual issue of a standard British year book appears under a slightly different title and in considerably altered form from its predecessors. The book is printed on better paper and in a new and more prominent type. The general index is transferred from the end to the beginning, and, for the first time, the book contains a large amount of advertising. At its close is published also a list of the principal medical works and new editions which appeared during 1914, a list of British medical institutions, homes, spas and sanatoria, and an official and trade directory. The text has been increased by 58 pages over the edition of 1914, and with the advertising and index makes a total of 1080 pages. The work presents an efficient and thorough summary of the year's progress in all branches of medical science, especial prominence naturally being given to the special articles on naval and military surgery. The new edition of the British pharmacopoeia is also carefully considered and the drugs noted in this volume have been unified in accordance with it by Dr. O. C. M. Davis of Bristol. The volume is the work of thirty-two distinguished contributors. Among the new names appearing this year are those of Dr. E. Wyllys Andrews of Chicago and Col. Louis LaGarde of the United States Army Medical Corps. Especially to be noted among the newer articles are those on abdominal surgery by Dr. Andrews, those on naval and military surgery by Dr. LaGarde, Dr. Cheatle and Dr. Wildey, and on shock by Dr. A. Rendle Short of Bristol. The book is more fully and effectively illustrated than ever before, with 71 full page plates, some of them colored, and 149 text cuts. The volume maintains its standard value and has many additional and unusual features of interest.

The Intervertebral Foramina in Man. By HAROLD SWANBERG. Chicago: Scientific Publishing Company. 1915.

This volume is published as a supplement to the author's previous monograph on the intervertebral foramen, reviewed in the issue of the

JOURNAL for April 23, 1914 (vol. clxx, p. 658.) It is intended to present the morphology of the intervertebral foramina in man, including a description of their contents and adjacent parts, with special reference to the nervous structures. The data upon which these observations are based were briefly reported in the *Journal of the American Medical Association* for October 31, 1914, and in the *New York Medical Record* for November 14, 1914, and January 30, 1915. Like its predecessor, this book does not aim to argue the question of the origin of diseases from spinal abnormalities producing pathologic changes in the intervertebral foramina, their contents or surrounding tissues, but merely aims to present a clear and concise description of the normal morphology of these apertures and parts in man. It extends Mr. Swanberg's research from the cat to the human being; and Dr. Harris E. Santee, in his introductory note, expresses the belief that, in the light of this research and of the new knowledge based thereon, "certain theories of spinal tension and compression must be greatly modified. The undoubted anatomic facts revealed in this painstaking scientific work necessitate a complete restatement of the *rationale* of cures effected by spinal manipulation." The work is illustrated with eleven original full page plates and employs the B.N.A. terminology throughout. It is issued from the anatomical laboratory of the Chicago College of Medicine and Surgery.

Applied Immunology. By B. A. THOMAS, A.M., M.D., and R. H. IYR, M.D., D.D.S. Philadelphia and London: J. B. Lippincott Company. 1915.

This monograph from the William Pepper Laboratory of Clinical Medicine aims to place within the reach of practitioners a knowledge of the practical application of sera and bacterins prophylactically, diagnostically and therapeutically. To this end accounts of experimental research are largely omitted and theories are presented only in so far as they may assist thorough comprehension, the primary object being to enable readers and students to apply competently to practice the principles underlying immunology. The subject is logically presented in a series of twenty-one chapters, each dealing with a definite aspect, and in an appendix there are three special chapters on the serum treatment of hemorrhage, on organotherapy and on chemotherapy. There is a brief alphabetic glossary of immunologic terms and the work is well illustrated with five colored inserts and sixty-eight figures in the text. It should prove a practical treatise of value in the clinical application of the knowledge acquired by research in immunology.

A Text-Book of Medical Jurisprudence and Toxicology. By JOHN GLAISTER, M.D.

D.P.H. (Camb.), F.R.S.E., Professor of Forensic Medicine and Public Health in the University of Glasgow. Third edition. New York: William Wood and Company. 1915.

This third edition of a standard work on legal medicine presents few extensive alterations from the second edition of 1910. Some of the chapters have been rearranged, others abbreviated, and some moderately extended, and there has been added a brief sketch of the general medical council, its duties, its statutory powers, with a full account of its penal resolutions. The book is well illustrated with 137 figures in the text and 1 colored plate. The index also has been made more detailed and complete. The work should continue to fulfil its useful function to students and practitioners of medicine and of law.

Annual Report of the Health of the Imperial Navy. For the Year 1911. Tokyo. 1915.

This belated annual report of the Japanese Imperial Navy Medical Corps presents in English version the morbidity and mortality statistics of that navy for the year 1911, based upon the same materials as that of the preceding year. The number of patients and the number of days' sickness show an increase over the preceding year, due to the increased size of the navy; but show a pro rata decrease compared with the preceding year and the average of the past fourteen years. The majority of the report consists of numerical statistic tables which are summarized, though not extensively interpreted, in the introduction. Accompanying this volume is the Japanese text of the report and also of the report for the year 1912.

Modern Aspects of the Circulation in Health and Disease. By CARL J. WIGGERS, M.D., Assistant Professor of Physiology in Cornell University, New York City. Philadelphia and New York: Lea and Febiger. 1915.

This monograph deals with the application of laboratory methods to the clinical explanation of obscure cardiac conditions, the understanding of whose nature and classification is part of the recent development of the modern study of cardio-vascular diseases. It is divided into three sections, the first dealing with the physiology of the circulation, the second with the graphic laboratory methods by which data about the heart and its action may be obtained, and the third with the phenomena presented by the various diseases of the circulation. At the close of each chapter is an admirable selected bibliography of the topic under discussion. The volume is a valuable compilation for clinicians of the newer methods of cardiac study and interpretation. It

is well illustrated with 104 engravings, chiefly of apparatus and graphic charts. It should prove a useful manual for students and practitioners desiring familiarity with the newest field of cardiac nosology.

Exercise in Education and Medicine. By R. TAIT MCKENZIE, B.A., M.D. Second edition, thoroughly revised. Philadelphia and London: W. B. Saunders Company. 1915.

The first edition of this standard manual of medical gymnastics was reviewed at length in the issue of the JOURNAL for February 10, 1910 (Vol. clxii, p. 184). This second edition has been almost completely rewritten in the light of the great advances in physical education which have been made during the past four years. The chapter on physiology has been expanded into four chapters. Especial attention is paid to the comparison and criticism of the German, Swedish and French systems of athletics and physical training. As before, the book is divided into two parts, dealing respectively with exercise in education and exercise in medicine. In the latter portion the chapters on medical gymnastic movements and massage have been expanded and rearranged and new chapters have been added on respiratory gymnastics, the treatment of visceral ptosis and functional disorders of the nervous system. The book is well illustrated with 478 figures in the text, and should continue its usefulness to physicians and educators.

Transactions of the American Pediatric Society. Edited by LINNAEUS EDWARD LAFÉTRA. Vol. xxvi. Chicago: American Medical Association Press. 1915.

This volume contains the proceedings of the twenty-sixth session of the American Pediatric Society held at Stockbridge, Mass., from May 26 to 28, 1914. The presidential address by Dr. Samuel McC. Hamill, of Philadelphia, deals with the responsibility of the pediatricist for the problems of public health. There are twenty-eight other papers on a variety of pediatric subjects. Dr. John L. Morse of Boston presents a study of the causal relation between the pasteurization of milk and infantile scurbutus; and Dr. Francis G. Benedict and Dr. Fritz B. Talbot continue their studies in the respiratory exchange of infants, with abundant tables and diagrams. The volume affords a useful contribution to the literature of recent progress in pediatrics.

Urgent Symptoms in Medical Practice. By ROBERT SAUNDREY, M.D. London: Edward Arnold. 1915.

This volume, by an eminent Birmingham phy-

sician, is intended as a reference work for practitioners and students on symptomatology. Such a book runs danger, in other than the most competent hands, of becoming a mere catalogue of symptoms upon which the inexperienced may rely for diagnosis and treatment in the absence of genuine medical knowledge. In the present instance, however, this danger is abundantly avoided. The work constitutes a valuable alphabetic collection of brief essays upon the significance of symptoms, from abdominal pain to yawning, and its use as a text-book should be of value to physicians even more than as a work of reference.

Studies from the Rockefeller Institute for Medical Research. Vol. xxi. New York: Rockefeller Institute for Medical Research. 1915.

This twenty-first volume continues the collective republication of reprints from various medical journals presenting the research work of the Rockefeller Institute. Among the papers constituting the present collection may be noted those of Flexner on the penetration of the virus of poliomyelitis from the blood into the cerebrospinal fluid and on the localization of the virus and pathogenesis of epidemic poliomyelitis. Dr. Peyton Rous continues his work on chicken tumors, on the cause of the localization of secondary tumors at points of injury, and on the greater susceptibility of an alien variety of host to an avian tumor. Jacques Loeb also continues his studies in fertilization and parthenogenesis. Dr. Alexis Carrel offers a report on the present (May, 1914) condition of a strain of connective tissue twenty-eight months old. He also presents the results of his work of last year on the surgery of the cardiac valves and on the technique of intrathoracic operations. The volume is well illustrated by many full page plates and text cuts, and constitutes a valuable archive of the progress of medical research.

A Manual of the Practice of Medicine. By A. A. STEVENS, A.M., M.D. Tenth edition. Illustrated. Philadelphia and London: W. B. Saunders Company. 1915.

The ninth edition of this standard medical handbook, prepared especially for students, was reviewed in the issue of the JOURNAL for Dec. 21, 1911 (vol. clxv, p. 959). In this tenth edition some of the chapters have been entirely rewritten and several new ones have been added. The number of pages is increased from 573 to 629. The plan of the book is unaltered. It is illustrated by seventeen text cuts. The additions which have been made deal chiefly with those diseases in whose knowledge recent progress has been made. The book should continue its usefulness as a convenient, clinical manual for students and practitioners.

THE BOSTON

Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, OCTOBER 28, 1915

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

The editor will be in the editorial office daily, except Wednesday and Sunday, from one to two-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

THE CLINICAL CONGRESS OF SURGEONS
OF NORTH AMERICA.

THE Clinical Congress of Surgeons, which is meeting in Boston this week, is an organization which has in the few years of its existence proved of great value to surgery in this country. The membership consists entirely of surgeons, and of surgeons who realize the importance of leaving home occasionally for clinical purposes. When the Congress meets in a city, the clinical forces of that city are mobilized, so to speak, and the various clinicians are prepared to show what lesson, if any, they have to teach their colleagues. The result is that in a short space of time, one gets a concentration of clinical work which in the scattered clinics of our cities can rarely be coordinated and made effective.

The evening meetings have been noteworthy always for the high character of the work presented and of the men taking part. The visiting

surgeons make these papers in the evening their contribution in return for the clinical program offered by the city visited. This year, the evening meetings are of special and timely interest. (The evening program was given in our editorial of October 14.)

The eminence of the Society's officers and the interest they have taken in the success of the Congresses has been productive of excellent results. The society has previously met in Chicago, Philadelphia, New York, and London, and most of those who have registered have been enthusiastic as to their value. Some of the earlier meetings were marred by overcrowding, but limitation of the number allowed to register, and the ticket system, have largely done away with that evil. The meeting in London was orderly, dignified, and of the greatest value to all who attended.

It is to be hoped that the meeting in Boston, with its famous hospitals, both old and new, and its excellent medical schools, may be of value to our visitors, as we know it will be to us who are honored by their visit.

AMERICAN FIRST AID CONFERENCE.

THE first meeting of the American First Aid Conference was held on August 23 and 24, 1915, at Washington, D.C. The deliberations of this conference culminated in the adoption of the following resolution, creating a board on first aid standardization for the purpose of studying first aid problems and standardizing methods, materials and equipment employed in the administration of first aid to those injured in the pursuit of industrial occupations and in war:

"Whereas, There is a great lack of uniformity in first aid methods; in first aid packages, and in other first aid equipment; and in first aid instruction, and

Whereas, Many of the aims of first aid are defeated thereby and needless suffering and expense incurred,

Therefore, Be it Resolved:

That this Conference recommends to the President of the United States that he appoint a 'Board on First Aid Standardization,' said Board to consist of one officer each from the Medical Corps of the U. S. Army, the Medical Corps of the U. S. Navy, the U. S. Public Health Service, the American National Red Cross, the American Medical Association, the American Surgical Association and the Association of Railway Chief Surgeons of

America; this Board to deliberate carefully on first aid methods, packages, equipment and instruction and to recommend a standard for each to a subsequent session of this Conference to be called by the Permanent Chairman; the creation and maintenance of the said Board to be without expense to the United States."

To attain the objects of this movement it is essential that this board should consult the best opinion of the country on the problems involved and should enlist the sympathy and active co-operation of medical societies throughout the United States. To this end the following resolution was also passed by the conference:

"That the questions noted below be sent to the Chief Surgeons of Railroads, Mines and Manufacturing, first, to be answered by them; second, that a copy of these questions be sent by the Chief Surgeons to their Associate Surgeons.

The object of these questions is to attempt to get the opinion and experience of a number of surgeons and to formulate them for publication.

Please answer each question on a separate sheet of paper and sign your name to each sheet:

1. What has been your experience with the most available first aid package and dressing for small and large wounds?

2. What has been your experience with the immediate employment of antiseptics in accidental wounds; what antiseptic have you used, in what strength, and how applied? Have you employed tincture of iodine? If so, how and what have been the results?

3. What in your experience has been the most efficient and most readily applied method of fixation for injuries of the (a) upper and (b) the lower extremity?

4. Have you considered the construction of a stretcher, which, in addition to serving as a means of transportation of injured, will have appliances for the fixation of the upper and lower extremity, somewhat along the lines of a Bradford splint, or the Gibon naval splint?

5. Please state your views on some liquid ointment dressing which would be available for first aid in large wounds and burns with the object of preventing the usual dry-gauze dressing adhering to the wound and rendering subsequent dressings painless."

The secretary of the conference, Dr. Joseph C. Bloodgood of Baltimore, has also sent to the secretaries of medical societies throughout the United States a circular letter, urging them to submit to the councils of their respective societies a resolution to appoint a special committee of three surgeons to study and deliberate carefully on first aid methods, packages, equipment and instruction. To recommend a standard for each to the National Board, and, through a spe-

cial representative or representatives, participate in the next American First Aid Conference which will be convened to consider the results of the labors of the National Board. The secretary of the conference, Dr. Bloodgood, will also welcome answers to the above questions from any surgeons of experience in the treatment of accidental injuries, and these answers will receive full consideration in the deliberations of the National Board.

This national movement for the standardization of first aid methods cannot be too cordially approved, since its purposes and ultimate ends are directed towards the establishment of a maximum of efficiency which will be of advantage not solely to this country but to the world at large, not in war alone, but even more importantly in dealing with the many and often inevitable traumata of peaceful industries. To obtain the prevailing opinion of the medical profession on these matters and to crystallize this opinion into safe guides for action there is need of the interested coöperation of all medical societies and of the individuals who compose them. The attention of the profession is, therefore, particularly directed to this new movement in an important department of national and professional proficiency.

THOMAS CAMPION, PHYSICIAN AND LYRIC POET.

AMONG the early English physicians who won even greater distinction in literature than in medicine, and yet are undeservedly little known or remembered, is Thomas Campion, an Elizabethan and almost exact contemporary of Shakespeare. His verse was rescued from oblivion in 1889 by the literary and critical labors of Mr. Bullen, who found in the British Museum the forgotten manuscript which contained the only surviving copy of Campion's writings. A few of his lyrics have since been turned to account by modern musicians, but the majority still remain buried in the old music books where they first were published. Of Campion as a physician, there is small record except that which remains in a few extant documents.

Thomas Campion was born of unknown ancestry in London in 1567. Of his youth nothing is known save that he was entered at the University of Cambridge in 1585, though he never matriculated, probably on account of his religious beliefs. In 1586 he was admitted a mem-

ber of Gray's Inn, presumably with the idea of studying for the bar. This purpose, however, was evidently abandoned, for not long after he appeared with a medical degree obtained from some unknown source and became a practicing physician in London. Apparently he was able to combine his literary with his medical vocation, for he continued in practice and maintained his professional interest throughout his life. Early in the seventeenth century he traveled in Europe and is known to have visited the medical schools at Padua, Paris and Louvain. He died at Loudon in February, 1620 (O.S. 1619) and was buried at St. Dunstan's Church in Fleet Street, where he is recorded in the parish register as "Thomas Campion, Doctor of Physicke."

Evidently during his life Campion, like many other English men of letters and physicians, held a fairly close connection with the court, though more probably in a literary than in a medical capacity. In 1607 he wrote a masque in honor of Lord Hayes (Sir James Hay), which was performed at Whitehall on Jan. 5, and in 1612 appeared his "Ode of Mourning on the Death of Prince Henry," eldest son of James I, who died of typhoid. In 1613 he produced three court masques, one for the marriage of the Count Palatine and Lady Elizabeth, another in honor of "our most gracious Queen Anne, in her Progress toward the Bathe," and the third for the marriage of the Earl of Somerset and the infamous Lady Frances Howard, the divorced countess of Essex.

There are few medical allusions in Campion's verse. Most notable in this respect are his lines addressed to one of his patients, "my honorable friend, Sir Thomas Mounson, knight and baronet," beginning

"I to whose trust and care you durst commit
Your pin'd health when art despaired of it."

This Mounson or Monson had been imprisoned in the Tower in 1615 and 1616 on suspicion of being concerned in the murder of Sir Thomas Overbury, and Campion, who served as a witness in his behalf, was allowed to visit him as his medical attendant during imprisonment. He was released in 1617.

Campion's reputation as a poet was evidently high in his own generation. William Camden mentions him with Sir Philip Sidney, Ben Jonson and Shakespeare as among those whom "succeeding ages may justly admire." John

Daines of Hereford wrote naively of Campion as follows:—

"Rare doctor with thy twofold art,
Hippocrates hath taught thee the one kind,
Apollo and the muse the other part,
And both so well that thou dost please

Campion's literary genius was essentially lyric and his songs are among the sweetest and purest of the Elizabethan times. He was at heart, what many poets have not been, a musician as well as a writer, and his verses, therefore, have not merely the balance of rhythm and the iteration of rhyme, but the qualities of tone and tune, possible only to one who has melody as well as cadence in his soul. He was also an author in the art of music and published a "New Way of Making Fowre Parts in Counterpoint by a most familiar and infallible Rule." Here he shows himself, too, a master of the melody and sweetness of prose as well as of music and verse, as for instance, in such a sentence as "There is no tune that can have any grace or sweetness, unless it be bounded within a proper key." Mr. Bullen, Campion's original editor, says of him, "even when matched for beauty of expression or surpassed for wealth of imagination, he is still the master of subtle cadences, a lord of haunting rhythm and delicate measures, whom in his kingdom few have approached and certainly none has surpassed."

It is unfortunate that we know so little of Campion as a physician, yet perhaps he was none the worse in his profession that he was a master of his avocation. In a recent address on British medical men of letters, before the Ilminster Literary Society, Dr. W. H. Maidlow* has called attention to the following quotation upon this topic from Bacon's "Advancement of Learning":

"Therefore I cannot much blame physicians that they use commonly to intend some other art or practice which they fancy more than their profession. For you shall have of them antiquarians, poets, humorists, statesmen, divines,—and in every one of these better seen than in their profession,—and no doubt upon this ground they find that mediocrity and excellency in their art maketh no difference in profit or reputation, for the weakness of patients and the sweetness of life maketh men depend on physicians with all their defects."

* Medical Press and Circular, Sept. 22, 1915.

ETHER DAY.

THE sixty-ninth anniversary of the first public demonstration of surgical anesthesia with sulphuric ether was observed in the customary manner at the Massachusetts General Hospital on October 16. At the afternoon exercises Dr. Henry P. Walcott, chairman of the hospital trustees, awarded diplomas to the graduating house officers and introduced the orator of the day, Dr. William W. Keen of Philadelphia. Dr. Keen delivered his address on "The Dangers of Anesthesia," reviewing the history of the subject since 1846, presenting extensively the statistics of various methods of anesthesia in different clinics, and suggesting that the discovery of new and more perfect anesthetic agents is yet to be expected. Dr. Keen's address is to be published in full in a later issue of the JOURNAL.

In the evening of October 16 the fifth annual meeting and dinner of the Massachusetts General Hospital Alumni Association were held in Boston at Hotel Vendome. Dr. James J. Putnam, retiring president, acted as toastmaster, and among the speakers were Dr. Keen, Dr. George C. Shattuck of Boston and Professors Lyman Kittredge and James Hardy Ropes of Harvard College. Dr. Shattuck described particularly his recent experiences in the work of the American Typhus Commission in Serbia under Dr. Richard P. Strong. The following officers of the Association were elected for the ensuing year:

President, Dr. Elbridge G. Cutler, '71, Boston; vice-presidents, Dr. Walter Channing, '71, Brookline; Dr. George K. Sabine, '72, Brookline; Dr. William S. Thayer, '89, Baltimore; secretary-treasurer, Dr. Byam Hollings, '01, Boston.

CENSORS' EXAMINATION OF THE SUFFOLK DISTRICT.

THE attention of recent medical graduates and of those practitioners in this Commonwealth who are not yet members of the Massachusetts Medical Society is called to the notice which appears on the last page of this issue of the JOURNAL, of the Censors' Examination for the Suffolk District, which is to be held at the Boston Medical Library on November 11. It is the duty as well as the opportunity of every physician practising in any state to become a member

of his state medical society. This, in addition to his official registration for practice, is an evidence to the public of his approval by his peers as a man competent to pursue the art and advance the science of medicine. Moreover, it incorporates him with his colleagues in all their endeavors for the larger promotion of the interests of the public health. Only by such united coöperation can the entire force of the medical profession be made effective for good in any community. To do this is the highest purpose of all medical organizations.

MEDICAL NOTES.

UNIVERSITY OF CALIFORNIA HOSPITAL.—It is announced that the University of California has received from an anonymous donor the sum of \$100,000 to endow memorial beds to Dr. C. W. Fox and his wife in the University of California Hospital. These beds are to be maintained in the new building of the hospital now being erected in San Francisco at a cost of \$615,000 as a part of the equipment of the Medical School of the University of California.

A MEDICAL SCHOOL AMALGAMATION.—Report from Philadelphia on October 16 announces the probability of a union between the Medico-Chirurgical College of Philadelphia and the Medical School of the University of Pennsylvania, the students and the medical equipment of the former institution to be transferred to the latter. It is also planned at the University of Pennsylvania, beginning with the fall of 1916, to extend the veterinary course in medicine from three to four years, and in the fall of 1917 to make a similar extension in the course in dental medicine.

INCREASE OF NAVY MEDICAL SERVICE.—In an address before the Philadelphia Medical Club on October 15 Rear Admiral Dr. William C. Braisted, surgeon-general of the United States Navy, advocated the establishment of a naval medical reserve corps to consist of 700 surgeons and 500 male trained nurses. He also advocated the increase of the active corps to 400 surgeons and 800 woman nurses. A two-year reserve supply of medicine and other necessities should also be accumulated in the event of emergencies and the addition of several new hospital ships is also urgently recommended.

NEW PRESIDENT OF STANFORD UNIVERSITY.—It was announced on October 15 that Dr. Ray Lyman Wilbur has been elected president of Leland Stanford, Jr., University and will assume that office on January 1, 1916. Dr. Wilbur was born at Boonesville in 1875 and is at present

the head of the medical department of Stanford University. He was president of the American Academy of Medicine in 1912-13.

LONDON DEATH RATES IN AUGUST.—Statistics recently published show that the total death rate of London in August, 1915, was only 11.6 per thousand inhabitants living. Among the several districts and boroughs, the highest rate was 16 in Poplar, one of the populous East Side slums, and the lowest was eight, in Wandsworth, an even more populous residential district on the South.

DETROIT ACADEMY OF MEDICINE.—The annual meeting of the Detroit Academy of Medicine was held in that city on October 12. The following officers were elected for the ensuing year: president, Dr. Charles D. Aaron; vice-president, Dr. Guy Connor; secretary and treasurer, Dr. Alpheus F. Jennings.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.—The forty-first annual meeting of the Mississippi Valley Medical Association was held at Lexington, Ky., on October 19, 20 and 21, 1915, with headquarters at the Phoenix Hotel. At the opening session the addresses of welcome on behalf of the city, of the local profession, and of the association were followed by the introduction of the president, Dr. Hugh Cabot of Boston. The meetings of the medical and surgical sections were held both morning and afternoon of each day. Among the papers presented at the various sessions were those on "Percussion Outlines of the Heart" by Dr. George C. Shattuck of Boston, "The Mechanics of Renal Infection" by Dr. Edward L. Keyes, Jr., of New York, "Cancer of the Gall Bladder" by Dr. F. T. Murphy of St. Louis, "Differential Diagnosis of Kidney Lesions" by Dr. Hugh Cabot and "Congenital Dilatation of the Colon" by Dr. Richard M. Smith of Boston. At the evening session on October 19, Dr. Cabot delivered his presidential address on "Medicine, a Profession or Trade?" The address in surgery was given by Dr. F. T. Murphy and the address in medicine by Dr. Richard P. Strong of Boston. It is expected that some of these addresses and papers may be published in subsequent issues of the JOURNAL.

NATIONAL ASSOCIATION FOR THE STUDY OF PELLAGRA.—The third triennial meeting of the National Association for the Study of Pellagra was held at Columbia, S. C., on October 21, and 22, 1915, under the presidency of Dr. C. H. Lavinder of the United States Public Health Service. At the afternoon session on October 21, there was a series of seven papers on the etiology, statistics and history of pellagra. Among these was a paper by Dr. A. C. Thomas of Foxboro, Mass., on the history of pellagra in Massachusetts. The evening session on this

day was devoted to a symposium on vitamins and pellagra. At the morning session on October 22, there were three longer papers reporting laboratory investigations of pellagra; and at the afternoon session on that day a series of ten shorter papers on clinical features of pellagra and five on the treatment of pellagra. On Saturday morning, October 23, there was held under the auspices of the South Carolina Board of Health a special meeting to take action upon a memorial to the state legislature for appropriations to further the study of pellagra and the care of pellagrins in the state. An effort is to be made to secure uniform action of state boards of health to lay these matters before their respective legislatures and the national congress.

PREVALENCE OF MALARIA, MENINGITIS, PELLAGRA, POLIOMYELITIS, SMALLPOX AND TYPHOID FEVER.—The weekly report of the United States Public Health Service for October 8, states that during the month of August, 1915, there were in Mississippi 25,998 cases of malaria, 1,787 of pellagra, 78 of small-pox and 1,106 of typhoid fever. During the same month there were in New York 17 cases of cerebro-spinal meningitis, 46 of poliomyelitis and 877 of typhoid. There were 91 cases of small-pox, and 25 of typhoid in Wisconsin.

EUROPEAN WAR NOTES.

RETURN OF MEMBERS OF HARVARD UNIT.—Report from New York states that on October 17, there landed in that city from Liverpool aboard the *Philadelphia*, six American surgeons returning from service with the Harvard unit in England and France. These were Drs. W. L. Lacey, W. A. Lane, W. J. Dodd, R. R. Sadler, C. C. Simmons and Paul Withington.

CHOLERA IN AUSTRIA-HUNGARY AND GERMANY.—During the week ended July 24, there were in Austria 2,040 cases of Asiatic cholera with 956 deaths, the majority of these being among the civil population. In Germany during the week ended August 21, there were 236 cases of cholera with 73 deaths, the majority of these being among the prisoners of war.

NEEDS OF AMERICAN AMBULANCE HOSPITAL.—An appeal has recently been issued by the board of governors of the American Ambulance Hospital at Neuilly, Paris, urging the need of further funds for the continuance of the work of that institution during the coming year. It is stated that the cost of maintaining the hospital is approximately \$1000 a day. Of the funds thus far subscribed only \$60,000 at that time remained, so that there is immediate need of raising \$350,000, to insure the continuance of the hospital for another year. The appeal states that the continuance of the hospital is earnestly desired by the French people.

"The funds on hand are barely sufficient to support the hospital for two months longer, and if Americans wish this work to go on, provision must be made at once in order that the American Ambulance will not have to close its doors for lack of funds. The governors of the American Hospital, the members of the Ambulance Committee, and the members of the American Committee believe that Americans will not be willing to consider such a possibility.

"The statistics show that the daily average number of patients in the hospital during June was 536. This number has been increased lately.

"The net running expense of the Ambulance for the nine months ending in June is given as \$206,644, but this does not include the heavy expenses of installing the new service, procuring new equipment and constructing new accommodations.

"A cable message reporting the progress of the three hospitals was received recently by Mr. Bacon from the Ambulance Committee. It read:

"Neully, France, Oct. 5.

"The hospitals at Neully and Juilly and the field ambulance service are running at high pressure and maximum efficiency. The patients under treatment are well above the normal capacity, but we are successfully coping with the emergency. The figures for Neully show that 3000 have been admitted since it was opened and 2400 discharged; 72,000 patients have been transported by the ambulance service. The field hospital is now well advanced and everything we can do is of great medical and real value, and will be of unperishable credit to the American people.

"The ambulance corps, which is a distinct feature of the service in itself, is composed of young volunteers, most of them recent graduates from American colleges and universities."

WAR RELIEF FUNDS.—On Oct. 23 the totals of the principal New England relief funds for the European War reached the following amounts:

Belgian Fund.....	\$275,042.00
French Fund.....	19,325.72
Armenian Fund.....	7,100.00
Surgical Dressing Fund.....	5,105.00

BOSTON AND NEW ENGLAND.

ELECTION OF OFFICERS OF THE BOSTON DISPENSARY.—At the annual meeting of the corporation of the Boston Dispensary, Edward R. Warren was elected president, Ashton L. Carr, treasurer; Dr. Edward C. Streeter, secretary; Charles M. Davenport, Mrs. Hilbert F. Day, Miss Alice DeFord, Lorin F. Deland, Mrs. Henry Ehrlich, Edwin Farnham Greene, Edward S. Grew, Randolph C. Grew, John F. Moore, Stuart W. Webb and Moses Williams, Jr., trustees. Michael M. Davis, Jr., was reappointed director.

It was reported that the work of the past year was greater than at any time since the founding of the institution 119 years ago. 120,368 pa-

tients were treated and the district physicians of the dispensary made 13,250 visits to the sick.

THE BOSTON DISTRICT INSTRUCTIVE NURSING ASSOCIATION.—The school of the Boston District Instructive Nursing Association has opened this season with thirty-nine students. Of this number, eleven nurses are students in the eight months' course, which is carried on in coöperation with Simmons College and the School for Social Workers, about twenty are taking a four months' course and five are from the senior classes in Boston hospitals who will do observation work in the regular daily duties of the association. Students have registered from Colorado, Minnesota, Illinois, Maryland, New Jersey, and New York; the New England States and Boston particularly supplying the greatest number.

DIPHTHERIA IN MALDEN.—Report from Malden, Mass., states that during the week ended October 16, 40 cases of diphtheria were reported in that city, 16 of them being in a single school. This school has been closed for several days by order of the local Board of Health and strict quarantine has been extended over all houses where the infection has occurred.

QUARANTINE AT BRIGHTON.—Although cattle from all over New England are being received for immediate slaughter at Brighton and sales are held on Friday afternoon, no public auctions are permitted to be held and no cows are allowed to enter the barn for purposes of sale. After the ten federal and state inspectors have twice visited the 1200 farms in the vicinity of Leicester and pronounced the district free from evidence of foot and mouth disease the barn at Brighton will be opened and auctions permitted.

HOSPITAL BEQUEST.—The will of the late Walter Whitman Hodges of Brookline, Mass., which was filed on October 16, for probate at the Dedham Court, contains a bequest of \$25,000 to the Boston Floating Hospital to constitute an endowment fund to be known as the Helen Ingalls Hodges Fund.

MILK AND BABY HYGIENE ASSOCIATION.—A recently published report of the Boston Milk and Baby Hygiene Association records the data of its third summer of special work in the prevention of infant mortality in Boston. From June to September, 1915, the Association supervised at its milk station the feeding of 2,997 babies and a total of 16,666 visits were made by its nurses to patients in their homes. The value of these visits is, of course, not solely alleviative but educational. The total attendance at the clinics for well babies was 9210.

The Association now finds the further growth of its work for which there is an abundant field hampered by lack of adequate funds and contributions to this end are, therefore, earnestly to be desired and urged. It is also particularly to be remembered that this

work is not limited to the summer season, but that to make its full value effective, it should be continued systematically throughout the year. Mr. Bedinger in his report, emphasizes this important fact as follows:

"The prevention of illness among babies in a great city like Boston is a task not only for the summer, but for every month in the year. Last summer's campaign was paid for by special gifts, but the maintenance and necessary improvement of our year-round service depends on our regular contributors and those who know the value of this work to keep babies well."

To reap the full fruit of the good work done in summer it is essential that means should be in hand to enable the continuance of this work the year around.

Miscellany.

BUREAU OF HEALTH, PHILIPPINE ISLANDS.

THE annual report of the Bureau of Health for the Philippine Islands for the year ended December 31, 1914, records the work of the department under the directorship of Dr. Victor Heiser. Dr. Heiser resigned from this position on the 28th of February, 1915, after twelve years of service, and the present commendable unitary condition of the Islands is a testimony to his efficient and untiring devotion.

In presenting his report he states as follows:—

"For the first time in the history of the Bureau of Health, no officers of the Bureau were imported from the United States, all vacancies being filled by residents of the Islands. Dr. Vicente de Jesus was appointed Assistant Director of Health on January 22, 1914.

"*Manila's Death Rate.*—The death rate for the city of Manila during the month of June reached 17.65 per 1,000 per annum, which is the lowest point which has been reached since American occupation. Owing to the appearance of cholera in the city, the result of the second half of the year was an increase in the death rate, so that the average for the year was 24.67 per 1,000 as compared with 24.98 for last year.

"*Soil Pollution.*—Most encouraging progress has been made in the campaign against soil pollution. There is reasonable hope that if the disposal of human excrement can be properly safeguarded it will result in an annual saving of at least 25,000 lives in the Philippine Islands.

"It is estimated that at least 90% of the inhabitants of the Philippines are infested with the form of intestinal parasite. As soon as the precautions against reinfestation become more generally adopted, it is the intention to take steps to rid the inhabitants of the parasites which they harbor, and the prospects of making great

improvement in the health of the residents of these Islands is, indeed, very encouraging.

"*Milk.*—The fresh milk supply of the city of Manila is still very unsatisfactory. A few dairies have complied with the standards of the commission on milk standards appointed by the New York Milk Committee, but the great bulk of the milk sold in Manila is handled under most insanitary conditions. On account of the fact that it is practically all collected by persons who own one or two carabaos and who are scattered over an enormous territory outside of Manila, it is impracticable at present to enforce the requirement of a modern dairy. It has been the hope to make the milk at least reasonably safe by proper pasteurization, and in order to accomplish this the Legislature made an appropriation to 'La Gota de Leche' Society for the Protection of Infants for the construction of a building in which may be installed the milk sterilizing plant which was donated by Mr. Nathan Strauss of New York. The erection of this building has been discouragingly slow, but the prospects now are that it will be available for use during the course of the next few months.

"*Canned Milk.*—Heretofore the poor quality of most of the fresh milk which is offered for sale in the Philippines has been largely offset by the importation of an excellent quality of natural whole milk, which can be bought under contract for large quantities in the Manila market for less than 24 centavos (12 cents) per liter (quart). The competition became so keen, however, that many dealers began to sell skimmed canned milk, which was placed in cans with most attractive labels, and as a large proportion of the public did not appreciate that skimmed milk was not a nourishing food for children, large quantities of it began to be sold. This practice has been effectively stopped by the Legislature placing an internal-revenue tax upon all skimmed milk, in whatever form, from which the cream has been removed entirely or in part, of 20 centavos (10 cents) for each kilogram (2.2 pounds) of gross weight of said milk and containers. This affords another instance where taxation has come to the rescue of sanitation in a most effective manner.

"*Cancer.*—During the early years of American occupation it was the general belief among medical men that cancer prevailed less extensively in the Philippine Islands than in the Temperate Zone. The opening of the Philippine General Hospital afforded an opportunity to study the disease on a large scale and under scientific conditions. While this experience has not been sufficient to draw definite conclusions, yet the indications are that cancer prevails as extensively in the Philippine Islands as elsewhere. Dr. George G. Davis, assistant professor of surgery, College of Medicine and Surgery, who has been on duty at the hospital, has recently reported 65 cases of oral cancer apparently very closely associated with the chewing

of betel nut and the buyo leaf. This habit prevails very extensively in the Philippines. A slice of betel nut is placed upon a buyo leaf, ordinary lime is sprinkled upon it, and then it is wrapped up in the leaf and the whole morsel is placed in the mouth and chewed.

"Cerebrospinal Meningitis.—The outbreak of cerebrospinal meningitis at the railway camp at Laguimanoc, mention of which was made in the last annual report, has completely subsided and only two authentic cases are known to have occurred anywhere in the Philippine Islands during the year. The diagnosis of these was confirmed by autopsy made at the city morgue.

"Cholera.—During the early part of July cholera made its appearance almost simultaneously in Manila and at a number of places in Rizal and Bulacan and Pampanga Provinces. So far as known, there had not been any cholera anywhere in the Philippine Islands for a period of several months. Careful stool examinations are made of all passengers coming to the Philippines from foreign infected territory, but no cholera carriers had been detected since January 10, 1914, so that it seems unlikely that the disease was introduced from a foreign country. The outbreak was very similar to that described for the previous year in the last annual report, so that it would be a mere repetition to mention it in detail. After the disease once had been established there was no difficulty in tracing the majority of cases in new territory to a previous case. The disease on the Island of Luzon slowly spread as far north as the Ilocos Provinces and a few cases also appeared in Aparri, Cagayan Province. It spread as far south as the Province of Tayabas. A small outbreak occurred in Capiz Province, which was directly traced to infection at Manila. Several cases appeared in Iloilo and these were traced to Capiz, but no spread took place. The energetic work of the health officers in a number of other provinces prevented the disease from getting a foothold there. In Manila cholera carriers were found in very large numbers and these were isolated at the San Lazaro Hospital under the same quarantine restrictions as true cholera cases. This had been done during the previous year, but this time it caused more opposition, which was, however, successfully overcome and the entire press of the city finally came to the relief of the Bureau by advocating the measure.

"Leprosy.—The treatment of leprosy with a hypodermic mixture of chaulmoogra oil at the San Lazaro Hospital by Dr. Eliodoro Mercado and at Culion by Drs. Paul Clements, José Martin, and Vicente Frias has continued to give encouraging results.

"The treatment will be given a thorough trial by the United States Leprosy Investigation Commission which is at present conducting work in the Hawaiian Islands. With the hope that the treatment might be further improved and placed upon a more scientific basis, the Sec-

retary of the Interior named a committee composed of Dr. John A. Johnston, chairman, and Dr. Eliodoro Mercado and Dr. L. Ordóñez, with Dr. Gervasio Ocampo and Dr. Luis Guerrero as honorary members to make a further study of it. This committee has placed 30 cases under this treatment.

"Smallpox.—The value of effective vaccination was still further demonstrated by the experience of the past year. Serious outbreaks of smallpox occurred among unvaccinated children and other unprotected persons, especially in the Provinces of Samar, Leyte, and Surigao. Many would, no doubt, have been averted if the local health officers had carried out the regulations of this Bureau which require that all unvaccinated persons shall be vaccinated during the months of July and January of each year. Some of the disease was due to the fact that it has been impossible to deliver potent vaccine into the more remote sections of the Philippines.

"There are many places that cannot be reached in several weeks from the place of the last ice supply. In this climate glycerized lymph cannot be depended upon to remain potent for a longer period than one week after it leaves the ice. For many years every effort has been made to solve this problem. The Bureau of Science has given much time and attention to it, as well as large manufacturing firms in Europe and the United States. Finally, one concern furnished a sample shipment of powdered vaccine which was kept for several months at ordinary temperature and then gave 85% of positive results in unvaccinated children in different series and under varying conditions. The total number of cases vaccinated being 79, with 61 positive 'takes.'

"A large shipment was then ordered, but this proved a complete failure. No better success has been had with a second shipment.

"The project of establishing a small vaccination laboratory in the remote country to be vaccinated has not been deemed practicable by the Bureau of Science. Further work in this direction is urgently demanded, because persons are dying of smallpox in remote places, who could be saved if successful vaccination were possible. Mr. Thomas Edison has interested himself in this matter with the hope of inventing a box that can be kept at a temperature of 0 C. for several weeks."

EFFECTS OF SELECTION ON ALKALOIDS IN BELLADONNA.

UNDER the title "Some Effects on the Production of Alkaloids in Belladonna," the United States Department of Agriculture in Bulletin 306 gives the results of a series of tests on controlling pollination of first and second generation plants, with especial attention to cross

pollination and close-pollination. The following are the conclusions reached in the bulletin:

"It having been established in the previous investigation that a wide range of variation exists in the alkaloidal content of belladonna plants, the present investigation was undertaken to determine whether the characteristic of alkaloid production is transmissible to the progeny through seed and whether the character is changed by vegetative propagation. The results thus far show that the first-generation plants secured from seed of cross-pollinated selected individuals display the characteristic of the maternal parent with regard to alkaloid productivity. This condition is generally true at all stages of growth during a season and also for at least two successive seasons. Close pollination of the parent plant has shown only a moderate influence on the transmission of this characteristic.

"Second generation plants from cross-pollination have been grown at Arlington, Va., Madison, Wis., and Timmons ville, S. C., and at all three stations they have displayed the relative alkaloid-producing tendencies evident in the original parent plant and the generation preceding.

"While the plants at the different localities showed a parallel relationship toward each other, there was considerable difference in the general quantity of alkaloids produced. Thus, in the case of Madison and Arlington, where two pickings were made at fairly corresponding stages of growth, it was found that the Madison plants yielded more alkaloids than those at Arlington. At Timmons ville the yield was still greater than at Madison, but here only one picking was made, and it is hardly possible to make a true comparison. Nothing definite developed to indicate that a relationship exists between the amount of precipitation and sunshine and the percentage of alkaloids produced.

"Plants were grown from cuttings, and at two stages of their growth these plants showed a marked tendency to display the same characteristic regarding alkaloid production as the plants from which they were propagated and the original parents of those plants."

PATENT MEDICINE PROSECUTIONS.

IN the issue of the JOURNAL for October 14 we commented editorially on the advertising of patent medicines in the daily newspapers and published also some further comment on recent patent medicine prosecutions. In the weekly report of the United States Public Health Service for October 8, 1915, is the following brief report of a further prosecution of the same nature. "The United States District Court for the Eastern District of Pennsylvania (see p. 3037 of this issue of the Public Health Reports) has decided that the Shirley amendment to the

United States food and drugs act is constitutional. This amendment makes it unlawful to print on the package or label of any drug false and fraudulent statements regarding its curative or therapeutic effects.

"The defendant was charged with misbranding a proprietary medicine which was sold under the name of 'Bad-Em Salz,' and with making false and fraudulent statements as to the curative properties of the remedy. The defense denied that the remedy was misbranded or that the label was calculated to mislead purchasers as to the composition or ingredients of the drug. It was also asserted that the statements relative to the curative properties of the drug were honestly made, that they were expressions of opinion, and that the defendant could not be convicted of crime merely because an opinion was expressed regarding the effects of the drug which differed from that of most physicians.

"The court held that the two questions (1) whether the name and label were such as to mislead purchasers respecting the composition of the drug, and (2) whether the statements regarding the curative properties of the drug were false and fraudulent, were both questions of fact which it was the duty of the jury to decide. The jury having decided both questions in the affirmative the conviction of the defendant was sustained."

In the weekly bulletin of the New York Department of Health for October 23 is reprinted a letter which has recently been addressed by a large firm of druggists, proprietors of several patent medicines, to pharmacists throughout New York State. This letter reads in part as follows:—

"The Board of Health of New York City is evidently trying to frighten the retail druggists so that they will not handle patent medicines. They say that after December 31 no patent medicines can be sold in New York City unless the formula is printed on the label or filed with the Health Department.

"It is unconstitutional to require the formula to be disclosed and we are not going to give ours up to the Health Board nor will we put it on the labels, but we want to assure you that you need have no fear of selling Doan's Kidney Pills, for if Dr. Goldwater should attempt to make any trouble for you on account of handling our medicine, we will back you up to the limit.

"The manufacturers of patent medicines are not afraid of Dr. Goldwater and there is no reason for you to be afraid of him. He is simply assuming a power that he is not entitled to and we shall not file our formulas with him until the last court in this country has so decided."

In its editorial comment on this letter, whose effrontery is an open defiance of law, the bulletin remarks that although the firm is not afraid of Dr. Goldwater, it is apparently afraid to let the truth be known about its remedies.

Correspondence.

WAR EXPERIENCES OF AN AMERICAN
MEDICAL STUDENT IN ITALY.

(From Our Special Correspondent.)

EDINBURGH, Sept. 29, 1915.

Mr. Editor: After crossing the frontier from France into Italy a difference in the people could be seen at once. It was something beside language or nationality. In France we had grown used to seeing old grizzled soldiers about the station, in faded uniforms. They seemed to take little interest in what went on about them. Even the passport inspectors were apathetic and did their work in a mechanical, tired manner. It was a different story when we reached Italy.

At the border our passports were stamped by the French authorities and we congratulated ourselves on having so little trouble. But at the first Italian town, Vingimille, we were examined and searched carefully. Officers came and went, demanded our itinerary, future plans and past history. The excuse of seeing the country seemed insufficient. Why did we want to look at churches and galleries in war time? We began to think it might have been better had we heeded the warnings given us in London that we might be turned back from Italy. Finally, after considerable consultation, they decided to let us pass, but we were informed that it would be necessary to remain in Vingimille till next morning. After depositing our bags in a hotel, we went for a stroll down the main street of the town, a street overarched by magnificent plane trees. It was the cool of the evening. Everyone was out to take the air. Groups of soldiers sauntered up and down, trying to look unconscious of their new uniforms and the admiring glances which followed them.

From Vingimille we traveled to Genoa and then on to Pisa. But the train was constantly held up to let troop trains pass through. It became necessary to change cars and wait some time at a junction town. The station was alive with soldiers. They looked very fine, many of them wearing broad brimmed hats with their fluttering cock feathers. Every uniform was new and unwrinkled. They were impatiently waiting to be transferred to the firing line. And they were a splendid lot of men to see—not tall, but strong and straight. Here and there could be seen a young officer examining a new revolver case with pride, or fiercely twirling his moustache while his thoughts went off to imaginary scenes of battle. How different they appeared from the tired-looking, silent soldiers of France! A year of war has sobered the French soldier.

However we were given little time to look about the station. Several officers approached us immediately and, looking at our passports, showed us into the waiting room and left us. We were delighted with their politeness, but when I started to go out into the town, I found that all the doors were locked. There was nothing to do but wait. Before long quite a party of officers came in, accompanied by a man who spoke English. They asked us the usual questions and handed our passports about curiously.

When we reached Pisa at midnight and found that we must register at the military station before we could go to sleep in the town, we began to lose patience. However, the man in charge of the office grinned broadly when he saw we were Americans and came forward to shake hands. "Sure thing," he said, he had been in America four years and would return as soon as the war was over. His income over there was many times what it was here although he had become an officer. "Yes," he said, "I come back. I drive a lee wagon in New York some more."

The longer we stayed in Italy the more we realized the tremendous enthusiasm running through the

country. The papers are filled with stories of the bravery of Italian troops. The war is popular with the people. They feel that at last Italia is taking her stand with the great nations and their pride and enthusiasm know no bounds.

WILDER G. PENFIELD.

BELGIAN PHYSICIANS' RELIEF FUND.

REPORT OF THE TREASURER OF THE COMMITTEE OF AMERICAN PHYSICIANS FOR THE AID OF THE BELGIAN PROFESSION FOR THE WEEK ENDING OCTOBER 16, 1915.

No contributions for the week ending October 16, 1915.

Previously reported receipts.....\$7,866.84
Total disbursements.....7,310.04

\$556.80

APPOINTMENTS.

HARVARD UNIVERSITY.—At a recent meeting of the corporation, the following appointments were made in the faculty of the Harvard Medical School for the academic year beginning September 1:

Dr. John L. Morse, associate professor of pediatrics, has been made full professor; Dr. Frederick T. Lewis, assistant professor of embryology, has been appointed associate professor; Dr. John Warren, assistant professor of anatomy, has been made associate professor; Dr. John L. Bremer, assistant professor of histology, has been made associate professor; Dr. Francis W. Peabody has been appointed assistant professor of medicine.

NOTICES.

HARVARD MEDICAL SOCIETY.—*Historical Club Meeting* in the Peter Bent Brigham Hospital Amphitheatre. Tuesday evening, November 2, 1915, at 8.15 o'clock.

PROGRAM.

Nathan Smith, Dr. F. C. Shattuck.
Nathan Smith's Essays on Typhus
Dr. H. A. Christian.
Nathan Smith's Essay on Necrosis.
Dr. W. T. Councilman.

Medical students and physicians are cordially invited to attend.

ERNEST GREY, Secretary.

CENSORS' EXAMINATION.

The Censors of the Suffolk District Medical Society will meet to examine candidates for admission to the Massachusetts Medical Society at 2 P.M. Thursday, November 11, 1915, at 8 P.M.

Candidates, who must be residents of the Suffolk District or non-residents of Massachusetts, should make personal application to the Secretary and present their medical diplomas at least three days before the examination, between the hours of 4 and 5 P.M.

DAVID CHEEVER, Secretary.

355 Marlboro St., Boston.

RECENT DEATHS.

The deaths of ARTHUR ERNEST GILLARD of Lowell, Mass., June 9, 1915, and CHARLES ARTHUR DEERY, of New Bedford, Mass., March 30, 1914, have been reported, but data as to place of death, age, etc., are lacking. They were Fellows of The Massachusetts Medical Society.

Address

MEDICINE—A PROFESSION OR A TRADE.*

BY HUGH CABOT, M.D., BOSTON,

*Assistant Professor of Genito-Urinary Surgery,
Harvard Medical School,
and*

*Chief of Genito-Urinary Department, Massachusetts
General Hospital.*

MEDICINE has always been regarded as one of the learned professions, and indeed this is a distinction of which we are particularly proud. But the tendency of a profession to degenerate into a trade is ever present, and is a danger from which more than one learned profession has been unable to escape. If Medicine is to avoid the downfall which has overtaken the Law it will be because we are more conscious of the dangers or more alert to check at the beginning undesirable developments. It is for this reason that I make no apology for calling to your attention some tendencies in the development of modern medicine which seem to me fraught with danger.

At the outset of any discussion of the professional or trade aspects of medicine, we shall do well to define our terms.

To me a profession is an occupation requiring an education in science, and which is pursued

for its own sake. It must have the advancement of science or the benefit of mankind as its chief end, pecuniary advantage being always a secondary and subordinate consideration.

A trade, on the other hand, is an occupation which is pursued chiefly, though not wholly, for the purpose of acquiring wealth; this wealth, with its ability to advance the interests of the individual, being the chief end.

In estimating the importance of any development in medicine we can best do so by comparing present conditions with those of the past. The changes which have taken place and the effect which they have produced upon the prevailing type of practitioner stand out clearly if we look back and picture to ourselves the type which was looked upon as the highest twenty years ago and compare it with the best that we are producing today.

The "big men" of twenty years ago, had without exception, gone through the school of general practice and had risen from the ranks to eminence by sheer force of character, being largely without assistance of the laboratory, and having fewer instruments of precision than we possess. They had trained their faculties of observation in the hard school of experience and had come to rely far more than we do today upon their individual judgment, unsupported by clearly demonstrable fact. They were more astute judges of men, with a larger comprehension of the strength and weakness of human nature and a wider sympathy. They were characterized by a certain boldness less seen today, bred of the necessity of staking their repu-

* Delivered at the meeting of the Mississippi Valley Medical Association, Lexington, Ky., Oct. 20, 1915. Simultaneous publication by courtesy of the *Lancet-Clinic*.

tations upon much less certain evidence. They seem to me to have been broader-minded, and rather more in touch with affairs other than those of medicine. Their devotion to the ideals of medicine I believe to have been more profound. Upon this latter point we have the direct testimony of a great surgeon in a lecture delivered nineteen years ago this month. Among other things he said:

"Medicine is the noblest of professions and the saddest of trades. As a trade it certainly is a very sad calling. . . In all other ordinary business trades the young man who is entering upon them advertises himself in some way; the doctor cannot advertise. . . He cannot sue others very well for his debts. . . because that savors of oppression. It is the taking advantage of other people's misfortune; it is taking advantage of their sickness and their weakness. . . The doctor, you must bear in mind, has to carry the burdens of all sick people; he is their friend, advisor and counsel, and if you look at it from a plain business point of view the fact must remain that this must be counted as a somewhat discouraging feature. . . Ours is the noblest profession that exists. It is above all the most humane; it cannot be otherwise; we seek daily and give our lives to make people happier, to make them better, to alleviate their suffering in every possible way."

This fairly expresses the ideals of the best type of practitioner developed under the conditions which existed a generation ago, conditions which developed character, which involved the ability to judge men, to make sound deductions from a study of character, and to come to a decision and act upon it as the result of weighing probabilities, not facts.

Since that time enormous advance has been made in every field of science as related to medicine. What we may broadly call "the laboratory" covering the fields of chemistry, bacteriology, pathology and physics,—has broadened the scope and increased the accuracy of medical diagnosis. Instead of being required to weigh probabilities we are today able to assort facts. Judgments of character have given place to assortments of data, and whereas the practitioner of a generation ago was profoundly influenced in his decisions by his study of the individual, the consultant of today may almost arrive at his opinion without ever seeing the patient. The amount of technical knowledge required of the physician today is enormously greater than was required of his predecessor, and it cannot successfully be denied that he is far more likely to arrive at a just appreciation of the facts.

With this advance, however, has gone the necessary division of medicine into specialties, a division which the rapid accumulation of knowledge has rendered inevitable, and this has sounded the death knell of the general practitioner.

His place has been taken, or rather is occupied, by the medical group, an aggregation or conglomeration of specialists, who having pooled the results of their investigations, are able with great accuracy to come to a diagnosis. These groups have developed either around the hospital as a center or around some individual, who, finding that medicine was growing away from him, has surrounded himself with assistants and associates equipped with special knowledge.

In its most finished form the medical group is represented by a hospital with medical and surgical chiefs, chiefs of special departments, and under each the necessary subordinates, but this development has been reached only by a comparatively small number. In a less obvious form, however, the principle is very widespread. Almost every internist or surgeon of large practice is in fact the head of a group, only it is unorganized and unnecessarily expensive. Each has an aurist, an oculist, an orthopedist, a dentist, a roentgenologist, a chemist, a pathologist, a serologist, who examines his patients, and on whose collective opinions his own diagnosis, prognosis and treatment must rest. Each one of us is a part of some more or less informal group, though the cohesion may be so loose as to more or less obscure the fact. This tendency to grouping is becoming more marked and the groups more formal.

There can be no question as to the efficiency of this method of "group medicine" in arriving at an accurate diagnosis and there can, I think, be no question of the necessity of such grouping in the successful development of scientific medicine. We may and do regret the disappearance of the well rounded general practitioner, but we must acknowledge the limitations of the human mind, and so bid him an affectionate farewell. We shall, however, do well to remember that this development carries with it certain serious disadvantages, the effect of which upon the type of practitioner developed may well be profound. "Group medicine" means diminished personal relation with the patient, less comprehension of character and personality, increasing probability of impersonality in the relation; in a word, the group tends to become a machine. Should this occur, the individual becomes a cog. Furthermore, the development of group medicine, with the increasing subdivision of medicine, has enormously increased its expense. Such groups require vastly more income than did the general practitioner whose place they have taken. It is this increase in the expense of medical practice which has fostered the growth of scandalous advertising, fee-splitting and the general exploitation of patients for money.

These are but the evidences of the development of the trade aspect of medicine, since all of them are not only proper but necessary in the conduct of any well organized business. Busi-

ness ethics require the giving of commissions to those who send trade. Business development requires advertising; business judgment requires that discovery be developed for the benefit of the discoverer. The increasing impersonality of group medicine makes the acquisition of the business point of view more easy. With the loss of the personal relation, the impropriety of taking advantage of the misfortunes of others slips into the background, while the necessity for maintained income from which to pay salaries becomes increasingly evident. A group must almost of necessity be managed upon a business basis. Salaries, if agreed upon, must be paid, and whereas the practitioner of former times had to think only of himself and of his family, the responsible head of a group must think of all the subordinate members of that group and of their families.

If it be a fact that most medical groups which have reached prominence in this country have been built up by advertising and fee-splitting, it is not so much a wonder that this has occurred as that it has not been absolutely universal. In the transition between individual medicine and group medicine this problem of income has pressed for solution and has been solved most easily by the adoption of business methods which require advertising and commissions.

We shall do well to look these facts squarely in the face and to decide as promptly as may be whether this development of group medicine is the logical method and if such be the case to lend it not only our support, but our criticism. It must be perfectly evident that the individual who undertakes to combine in his own person all the functions of the members of such a group will inevitably fail and that the replacement of the general practitioner is already complete for such portions of the country as are thickly populated. We shall do well also to recognize that this development seriously threatens the professional character of medicine and that unless it be carefully safeguarded the professional character will be lost. For my own part, I am entirely convinced that the group must take the place of the individual and that the possibility that medicine will be converted into a trade can be avoided by clear recognition of the danger.

We shall doubtless be tempted to ask whether such a system of medicine tends to develop men of a calibre equal to their forefathers; and whether this business organization tends to develop as high a type of practitioner. The answer to these questions is of course difficult, for certainly it will tend to develop an entirely different type. More and more the heads of these groups will become experts like any other business expert and likely to hold a similar position in the community. The "big men" in medicine will be more like the big men in business. They will cease to be the guide, counsellor and friend of the individual, but may perhaps

become the guide, counsellor and friend of the community. Their present position in the community will probably be lost, but they may acquire another, perhaps better suited to modern conditions. Since the development of medicine has made it impossible for them to do justice to their patients without much assistance from others, they must be content with their altered relation, but this change does not require the abandonment of the ideals of a profession and the assumption of the character of a trade. It is wise, however, to appreciate that the scale is narrowly balanced and may readily tip in such a way as to spill its contents from a profession into a trade. If this is to be avoided it must be by a willingness to face the facts and deal with them. The chief difficulty lies in providing a proper income for the support of these medical groups. At the moment it is being provided by a competition which has many dangerous possibilities. Competition is the essence of growth, but competition may be of more than one kind. Competition in a trade is, grossly speaking, for a money reward; competition in a profession is for scientific achievement. If competition in medicine is to be for both money and scientific achievement then money may well gain the upper hand. Competition between medical men for money when lives are in the balance is intolerable, and yet no one of us can honestly deny that such competition today exists and that it is at the root of most of the worst tendencies against which we have to strive. If medicine is to remain a profession this competition for money must cease.

Now if we are to remove from the field of medicine this undesirable kind of competition then all practitioners of medicine must be paid salaries, and the amounts of these salaries must be determined by persons having no personal interest at stake. This means, reduced to its simplest terms, that we have a choice between the taking over of medical practice by the state or the management of medical practice from institutions or hospitals as a center. In either case, salaries must be paid to all, and the temptation to practice medicine for money must be eliminated as a possibility. The choice between state medicine and hospital medicine must be determined ultimately by the peculiarities of the civilization concerned. Personally, I have an abiding dread of state medicine in a democracy, because of my recognition of the essential inefficiency of democracy. Whatever may be the beauties of this form of government, efficiency is not among them, and though I quite realize that it is possible to worship efficiency as a goal to far too great an extent, I also recognize that inefficiency in medicine may well prove a fatal defect. I cannot construct any theory of state medicine in a democracy which does not appear to me likely to ruin not only the democracy but medicine. I therefore look forward to the development of group medicine with the hospital

as its center, such hospitals to be under the management of trustees, who, it is to be hoped, will take their duties much more seriously than do most trustees of today.

It will probably be objected that this will involve the treatment of all patients in institutions but this will not of necessity result unless it be thought desirable. There is no substantial objection to the hospitals' staff making visits at any reasonable distance without loss of the important advantages of medical grouping. It does not even seem to me impracticable to conduct country practice in sparsely settled districts upon a hospital basis. It would seem to me entirely feasible to use the towns and smaller cities as centers from which medicine should radiate. The younger members of the organization would do the work in the outlying districts, living there if necessary, but always keeping in close touch with their hospital center, and being promoted as experience and opportunity should dictate. It would thus come about that the younger practitioners would have thrown upon them the more laborious work, while the older members of the group would occupy the positions requiring rounder judgment and fuller development but neither the activity nor the enthusiasm of youth. We might in this way preserve all that is best in competition for that scientific achievement. We could undoubtedly permit the development of individuals along the lines best suited to their peculiar capacity, and get from each what he was best able to give. We should avoid the scandals of inhuman charges and of indecent exploitation of suffering humanity by the sharks of the profession, and we might well avoid the tragedy by which the impecunious young doctor must select general practice, for which he is ill equipped, because he cannot afford to devote himself to the pursuit of pure science, for which he is best fitted.

I cannot leave this subject without admitting that I am not unmindful of the undoubted defects of the system which I have just described. I do not for a moment overlook the danger that we may come to regard efficiency as a god, that we forget that the individual is a patient and think of him only as an instance of disease. I am not unmindful of the danger of losing that broad culture which was developed in the physicians of the last generation. But these dangers seem to me largely avoidable if clearly appreciated. I cannot doubt that the pursuit of science will always bring out inherent qualities of greatness. I cannot doubt that the care of the sick will always develop the humanities and I cannot doubt that a profession which has for its sole aim and object the mitigation of the sufferings of mankind will attract to itself men with the same inherent possibilities for greatness that have always characterized the followers of Aesculapius.

LATE RESULTS OF OPERATIONS UPON HIP JOINTS FOR HYPERTROPHIC ARTHRITIS.

By E. G. BRACKETT, M.D., BOSTON,

AND

H. W. MARSHALL, M.D., BOSTON.

[From the Orthopedic Clinic of the Massachusetts General Hospital.]

TWENTY patients from the orthopedic service of the Massachusetts General Hospital were asked to return for observation upon the late results of operations on their hips. A few could not be found, some lived at too great distances to return, one had died, and only nine finally were seen.

This small number, nine cases, however, is convenient for indicating some of the possibilities of surgery in these social conditions, and the cases will be reported individually as well as in a group. The various circumstances associated with the cases also will be discussed, for benefits of operative interference can be judged most correctly by taking into account the different elements that enter into the background of each surgical picture.

These patients can be described as presenting either (a) monarticular defects or (b) polyarticular ones with marked hip involvements.

(a) Monarticular processes very frequently appear to be excited by definite traumata.

(b) Polyarticular lesions occur after numerous infections and chronic metabolic defects, but in this paper only the residual joint changes that remain after all active processes have entirely subsided will be considered. Exact natures of these residual effects are obscure as they usually represent combined results of a number of factors. All, however, are characterized by more or less overgrowth of bone around the joints, and local hip conditions with their surgical treatments therefore will be given great prominence in this paper.

Ages of patients range from young adult life to old age, the majority having reached or having passed middle age. They all present painful, stiffened, damaged joints with marked degrees of disability; and crippling disability is the deciding factor in every case that determines the time for surgical interference.

Two important varieties of operations have been performed: Firstly, removal of small bony prominences around acetabula and heads of femori in hip joints still fairly normal apart from these protuberances; and secondly, more extensive operations in disabled hips. There are two subdivisions of extensive operations, namely (a) arthrodeses intended to secure firm union and complete stiffness of the joints in most desirable

positions; and (b) decapitations of femoral heads in order to allow increased, though limited motion at the sacrifice of some stability.

Cases in which removal of small, isolated osteoarthritic prominences is possible with very distinct benefit are not numerous. The ordinary bony overgrowth, even though extensive, as a rule does not interfere materially with the amount of motion of the joint, as it usually permits as much motion as damage within the joint and in the more or less affected capsule will of itself allow independently. In a few instances, however, overgrowths are so located, under the Y ligament for instance, as to mechanically limit certain motions. Removal of these sharply localized exostoses under these conditions leave affected joints in greatly improved functional states.

The choice of extensive operations often is quite difficult and they should never be thought of until practical disability is nearly complete. In making decisions the following points have to be kept in mind:

(a) The nature of the arthritic process, whether it is a part of a general systemic disease or the residuum of a toxic state that has entirely disappeared.

(b) The involvement of other joints, particularly in the opposite leg.

(c) The degree of disability in its relation to the patient's occupation, social standing and habits of life.

(d) Age of patient.

It is natural that judgments should vary according to social conditions of patients. The working poor will frequently arrive at disabled stages much earlier than sedentary well-to-do people. In the former, relief by operation often becomes a necessity, which in the latter will always remain a choice of expediency.

In multiple arthritis extensive operations are reserved particularly for residual disabilities in which there are reasons for feeling that further progress will not be probable. The existence of multiple joint involvements seriously complicates operations when the processes involve both hips or both knees, or one hip and the opposite knee. In the end, however, in all cases degrees of disability are the deciding factors, and the most important element in disability is that of pain, particularly pain following use. Extensive operations are not to be considered in active nor even in doubtful stages of infections, nor in any steadily progressive lesions.

There are two operations of choice in severe cases, as already stated. Excision of the head of the femur leaving the acetabulum with its lining cartilage intact is designed to retain motion in the hip, although resulting in a somewhat less stable joint for standing or walking. Arthrodesis of the hip joint with removal of the cartilage from acetabulum and femoral head, gives increased stabil-

ity in standing and walking as a result of the complete stiffness which follows, but with greater inconvenience in sitting. Arthrodesis must be considered a final operation, whereas excision of the head of the femur may be followed later if necessary by an arthrodesis.

In the choice between the two, the social status of the patient again is a matter of very great importance, and before decision is made there also must be thought of: (a) the integrity of the acetabulum; (b) the amount of capsular contraction and thickening which diminishes the intra-capsular cavity of the joint; (c) the amount of osteal change of the neck of the femur; and (d) the age of the patient.

Limited degrees of motion always are desired after decapitations of heads of femori; and it is doubtful if more than 35° is desirable in any case, for the reason that greater excursion produces greater mechanical irritation with resultant greater tendency toward further bony changes. Finally, it should be distinctly recognized that removal of offending bony overgrowths and surgical treatments do not terminate always underlying pathological processes which have produced the hypertrophic defects. The latter may continue at times and very gradually limit again motions in operated joints.

GROUP STATISTICS.

The ages in the nine observed cases have ranged from 29 to 57, with an average of 35 years. Three are women and six are men. Five of the persons are at work at present, on an average time of three years and three months after operation, varying within the limits of two years and two months to four years and nine months. Four are fairly comfortable and able to get around with canes or crutches, and none are completely helpless. Among the four who are not at work two were favorably enough impressed by their surgical experiences to come back for a second operation upon the other hip joint, having been as much pleased with the first results, as the five active ones now are with their respective treatments. One chronic hip in the series proved to be tubercular and required two trials for immobilization. It is firmly ankylosed now and the patient walks with a cane.

It is difficult to obtain a clear idea easily of the actual benefit derived from operations in these cases as the patients never can be extremely active, vigorous individuals again, although perfect surgery is practiced. They show before operation already the effects of serious wear and tear of life and these effects cannot be entirely removed. An illustration is given in Case 1, a man of 57 who now has a hip with 30° of flexion, complete extension and 15° each of adduction and rotation seven years after surgical interference. He has very little pain now, and this late result though far from perfect, represents nevertheless, a more useful joint than the painful one with which he came for treat-

ment. Seven years of relief from pain alone is a considerable benefit.

All nine patients who returned for observation had suffered severe pain before their admission to the hospital and all were more or less relieved from this symptom after surgical care. This fact alone should possess considerable weight favoring surgery, apart from any relief of existing anatomical defects.

NON-OPERATIVE MEASURES.

The present paper deals mainly with late results of operations but the pre-operative histories indicate in a general way what human natures will endure before patience is lost, and relief from suffering and disability is demanded through radical surgical measures. On an average in the nine cases reported, surgical interference occurred four years after onset of symptoms, ranging from eight months to eleven years, depending on severity of pain and degrees of disability. During the periods before operations patients received hydrotherapy, medico-mechanical treatments, immobilizations in plaster casts, foot plates, crutches, diets and internal medications. Four received hydrotherapy, one having 39; one, 10; one, 13, and the other person 12 treatments. Four received mechano-therapeutic measures. Special diets were prescribed frequently, once with obvious success; and medicines were given rather sparingly.

The minute details of these various non-operative therapeutic procedures are too tedious to be reported, yet upon their correct prescription depend results to important degrees. For example, when patients are given massage and local stimulating exercises which produce too great local irritation, these individuals then come more quickly to operative stages than they would otherwise; but it is to be remembered that many persons who have mild hypertrophic conditions never come to operation because some of them find relief in the same mechanical measures and immobilizations that aggravate others. Diet regulations undoubtedly have important influences upon articular conditions, but it must be admitted that we prescribe our non-operative treatments unskilfully quite frequently in the absence of reliable delicate indicators of their actions. When physicians are unsuccessful or when diseases are unusually obstinate, sooner or later, patients become weary of all measures which do not afford relief in a reasonable length of time, and they turn then to orthopedic surgeons.

After-care of surgical cases belongs in a class similar to pre-operative treatments, being very important yet frequently very difficult to regulate. An illustration is furnished by Case 1 of this series. One leg of this individual is in good position and is a useful member after prolonged care, while his other leg is comparatively useless following equally good surgery

under identically the same variations in health. The second result seems due, in part at least, to the patient's neglect in after treatment. Apparently he exhausted his patience in the long physical therapeutic courses following the first operation, because he did not return for several years to the hospital after his second surgical experience. It is an injustice to attribute the poorer results of the second operation to surgical causes when they more properly represent the limitations of human perseverance.

SUMMARY.

The nine reported cases represent four arthrodeses, one decapitation of the femoral head, three cheilotomies, and one arthrotomy for a loose body.

Results of the four arthrodeses are as follows: Three patients were actively at work at the time the last observation was made on them, and the fourth person was improved in health. One, a sea captain, returned to work in six months after operation and was still occupied in this way three years afterwards. The second, a laborer, returned to work in five months and was employed thus after four years and nine months. The third, a woman, was working in a lodging house three years and eleven months after surgical interference, having been able to return to an active life in six months. The fourth patient, also a woman, was much improved in general health when last seen four years after her first surgical experience; but although she could walk without a cane she had not recovered enough from her long difficult convalescence to handle her stiffened hip perfectly.

The result of the decapitation of the femoral head represented some improvement. The patient, a laborer, was in good health after two years and two months, and could walk about his home as much as he wished without pain with the aid of a cane, but he was not engaged in regular work. The three cases in which diffuse exostoses and bony lips were removed from hip joints (cheilotomies) varied considerably in their success. One, a teamster, was at work two years and ten months after operation, having begun again seven or eight months after leaving the hospital. The other two patients had both hips operated on, and neither had resumed his former occupation. One of the two could chore around home and did not need a cane except in the street. It is a question whether he would not have received greater benefit by an arthrodesis on one hip. The last observation was three years and five months after he left the hospital. The third cheilotomy case was operated on twice and walked with a crutch and a cane seven years after his first operation. At this last observation which was made he was in fairly good general health with much less hip pain. The first joint of his which was treated was still quite serviceable, while the second one was neglected by

him in its after care so that it was badly rotated outwards at the last examination. This case, the oldest of the series, originally had marked changes in both hips and had been disabled for two years. His efficiency was increased by surgery but not to the point of work, and the main benefit has been in relief from pain.

The one case of arthrotomy for removal of a loose body in the joint probably had a traumatic origin, and at operation the joint did not show many other pathological changes. Complete relief followed removal of this body and the patient could walk easily and painlessly when seen after two years and one month. She then was looking for work.

In conclusion it can be said that the choice of operation should be made with great care, dependent on the amount of destruction, the number of joints involved, the social position of the patient and the kind of work which afterward will be demanded of the joint. Efficiencies of patients may be expected to be increased and the pain relieved by surgery. None of the patients have been made worse by surgical interference and it accomplishes enough to justify itself in those cases which have become seriously disabled, by simply relieving continuous pain, or in quickly stiffening some joints to useful positions, or in prolonging their functions and activity. Surgery does not remove the tendency to continued overgrowth if the source of infection in the multiple arthritis cases is not removed, but there is much less tendency toward recurrence in monarticular traumatic cases.

INDIVIDUAL CASES IN DETAIL.

CASE 1. E. W. Well-developed man of fifty years. Stevedore. Both hips operated on, the second one five years after the first, at the age of fifty-five.

In the left hip at operation a small piece of bone was found on the acetabular margin that interfered with motion and this was trimmed away. There was a small amount of clear fluid in the joint cavity, and the head of the femur was dotted with small rough granules on its articular surface. After recovery much improvement in range of hip motions was noticed immediately, then progressive hypertrophic processes very slowly limited these motions again. Before operation flexion was slightly limited, complete extension was possible with no hyperextension. Abduction and adduction were one-third normal. Pain and crepitus were noticed on motion. Seven years after surgical interference, flexion through 30 degrees was possible with complete extension and with abduction, adduction and rotation each of 15 degrees. At this last observation there was very little pain that previously had been complained of, although joint crepitus persisted.

In the right hip at operation the capsule of the joint was found thickened and hypertrophic processes distributed on the femoral head. The articular edges of acetabulum and head were curetted and smoothly trimmed. Before operation the right hip was permanently flexed 10 degrees, with passive flexion of 55 degrees, and with no inward rotation. It was held in outward rotation and there was pain on motion. Shortly after operation complete ex-

tension was possible, flexion of 40 degrees, abduction of 10 degrees.

Pain on motion disappeared quickly but inward rotation still was impossible. Two years after operation there were a few degrees of permanent flexion and 25 degrees of passive flexion but this was also necessarily accompanied by abduction of the thigh. Rotation was possible then between limits of outward rotation of 35 degrees and 50 degrees; and there were slight hip pains on motion.

The patient came to the Massachusetts General Hospital first complaining of nipping pain and creaking in both legs of two years' duration and gradual onset. He had never had any serious illness, had eaten heartily and drank alcoholic stimulants freely for years but not to great excess at any one time. Hypertherapy first was tried for two months then the first operation was advised. Following it, but previous to the second one, prolonged courses in hydrotherapy and mechano-therapy were received. Pains in the operated hip subsided during this interval while simultaneously symptoms in the right hip gradually increased up to the time of the second operation. After the second surgical interference he was not heard from for two years, having become tired of the frequent visits to the hospital necessary for physical therapy.

When last observed he was walking with crutches, the right leg too much averted to be useful. His general health and muscular strength, however, were still good although he had been unable to perform the active duties of stevedore since the onset of his trouble.

CASE 2. L. W. Well developed man of fifty-three years. Sea captain.

The right hip was found at operation to have the joint capsule bound down obliterating the joint cavity; also the muscles about the joint showed evidences of chronic inflammatory process. A wedge-shaped piece of bone was removed from the head of the femur; and the acetabulum after curettage was allowed to unite firmly with the head of the femur.

Before operation the thigh was flexed at ninety degrees and adducted forty-five degrees. Muscle spasm held the hip nearly rigid, but under ether there was a relaxation to forty-five degrees of flexion and ten degrees of permanent adduction.

Three years after operation at the final observation the thigh was firmly ankylosed in fifteen degrees of flexion, ten degrees adduction, with the foot pointing nearly straight to the front. He then continued to work as captain of a steamer, had no pain, used no cane, walked with a slight limp and was in good health.

The original trouble came from septicemia which developed after an injury to the thumb. During convalescence from this poisoning the hip became involved and continued to become inflamed at intervals for a year's time until he finally came to the Massachusetts General Hospital. Six months before the hip joint was opened the adductor muscles were tenotomized and the leg held straightened in a spica, and during this period the patient gained twenty-five pounds, recovering nearly completely his healthy vigor.

CASE 3. A. J. Well developed man of fifty-one years. Laborer.

The capsule of the right hip joint was found thickened at operation, and nodules were cut away from the neck of the femur. An exostosis, size of a

marble, was removed from the trochanter. Cartilages of the hip joint were normal.

Before operation the patient had a limp, showed marked lumbar lordosis and walked without crutches. His leg was held in a position of permanent flexion of 15 degrees with considerable permanent outward rotation, also there were 45 degrees of flexion without adduction or abduction. The thigh and calf muscles were much atrophied.

Two years and ten months after operation the thigh was held normally extended, and there were 10-15 degrees of flexion but without rotation or abduction. He had gained in weight, thought his operation a benefit, and was able to work driving a water cart. He used a slender cane part of the time to favor the leg, and found that a laborer's work of continuous shovelling of dirt tired the hip.

The onset of hip symptoms originally began suddenly eight months before surgical interference, and there had been no severe trauma. For four or five months at first he was treated with rheumatic remedies, but steadily grew worse and then came to the Massachusetts General Hospital. X-rays taken there showed very definite hypertrophic overgrowths and an operation was soon advised. For five months after dismissal from the hospital ward, following operation, he returned at intervals for baths and medico-mechanical exercises. These he considered helped him considerably in regaining strength and motion in the leg.

CASE 4. S. P. Small woman of twenty-nine years. X-rays showed considerable destruction of the head and neck of the femur and the joint was opened. Several pieces of loose bone were removed, and the acetabulum was curetted and chiselled to fit the upper end of the femur. The wound was closed and a plaster spica applied. A second operation became necessary on account of mobility and pain two years later. Then an old sinus below the trochanter was curetted and fresh surfaces were made in the joint, so that solid union was obtained ten or eleven months after this second attempt.

Before operation the hip was held in 30 degrees permanent flexion, 20 degrees adduction and 10 degrees outward rotation. Motion of 10 degrees was possible with pain.

Four years and three months after the first surgical interference the patient walked with the leg solidly fixed in permanent flexion of 25 degrees, adduction of 10 degrees, and with very little discomfort aside from a slight stiffness at first on attempting to walk.

She originally had had hip trouble as a child and had worn a high heel. Two years before coming to the Massachusetts General Hospital she slipped and strained the joint, and then developed increasing pain and local tenderness up to the time of surgical interference. Examinations of the pathological tissue later showed this case to be a very chronic tubercular hip.

CASE 5. P. D. Healthy-looking man of fifty-seven years. Laborer.

At operation the rim of the acetabulum and the edges of the articulating surface of the femoral head presented abnormal bony overgrowths and these were removed. The articulating portion of the head was cut away considerably.

Before operation the thighs could be separated only eleven inches between the femoral condyles. The left hip, which was treated surgically, was nearly

completely extended but hyperextension was impossible. There were 45 degrees of flexion which was painful as the limit was reached. Internal and external rotation were both limited.

Two years and two months after operation the leg was held completely extended, and exhibited 5-10 degrees of flexion. There were 5 degrees of permanent adduction and 55 degrees of eversion. Adduction, abduction and rotation were absent. Shortening of 1½ inches. No pain was noticed.

The patient had been troubled five or six years before coming to the Massachusetts General Hospital. X-rays showed marked hypertrophies of both hip joints and operation was soon advised. He received nineteen physical therapeutic treatments during the three months following his dismissal until the last observation was made. At the last observation he was in good health, used a cane, and walked about his home as much as he wished.

CASE 6. J. L. Small man of fifty-three years. Salesman.

X-rays showed many pathological changes in both hips, and both hips were opened, an interval of four months occurring between the two operations.

The left hip at operation showed a thickened capsule and small amount of joint fluid. The femoral head was flattened and mushroomed. There were large exostoses on the rim of the acetabulum. These abnormal overgrowths were all removed. Before operation the joint could be flexed 85 degrees with pain, and adduction and abduction were somewhat limited. Three years and nine months after operation full extension was possible with 30 degrees of painless flexion. The foot pointed straight ahead and a few degrees of rotary motion were possible. Abduction of 15 degrees and adduction of 5 degrees.

The right hip at operation showed a thickened calcified capsule. The head of the femur was flattened and mushroomed, and exostoses were found around the edge of the acetabulum. All rough nodules were removed. Before operation there was complete extension and 75 degrees of flexion. Outward rotation was difficult and limited to 15 degrees. No hyperextension nor inward rotation. Adduction one-third normal. Grinding pain on motion. Three years and five months after operation there were 55 degrees of flexion, complete extension, outward rotation of 25 degrees, no inward rotation, adduction of 10 degrees and abduction of 15 degrees. Less pain on motion.

The patient had had pain in the right hip for eleven years, and for several years in the left one before operation. Finally the left side became so painful that he could not work and he came to the hospital. Hydrotherapy was tried first for two months, but good effects seemed to be neutralized by exposure to cold after the baths. He carried crutches or a cane for four months after the first operation until the second one; but he wanted the second surgical treatment because the operated hip felt so much stronger and because it had a good range of painless motion. When last seen he considered his operation a benefit, although he had not worked except around home. He did not use a cane except in the street and he enjoyed good health, and had less hip pain.

CASE 7. M. O. Poorly nourished, fairly well developed woman of forty-three years.

At operation the joint cavity was found entirely obliterated. A layer of cartilage and bone was re-

moved from the femoral head, and the acetabulum was eurented and deepened for the denuded head to fit into firmly.

Before operation there were 30 degrees of permanent flexion and 20 degrees of permanent adduction with practically no hip motion and no tenderness in the hip. Three years and eleven months after operation there was solid ankylosis with permanent flexion of 15 degrees and permanent adduction of 15 degrees. The foot pointed straight front. Actual shortening of one-half inch. Apparent shortening $1\frac{3}{4}$ inches. No pain. Walked without crutches. Health improved.

The origin of this arthritis was obscure, having come on gradually three years before operation, and increasing until she became incapacitated one year before surgical interference. She thought her operation a great benefit.

CASE 8. D. H. Small woman of thirty-seven years.

At operation a small almond-shaped mass, the size of a bean, could be felt inside the capsule just before it was opened over the femoral head near the cotyloid ligament. When the capsule was cut this was removed, and a sharp ridge on the edge of the femoral head was smoothed away.

Before operation there were irregular snappings and catches in the inguinal region on rising from sitting or kneeling postures, but there was no difficulty in ordinary walking or standing. The hip joint seemed to lock for a moment, and by slowly twisting it the patient was able to restore normal motion again. Flexion was possible to 90 degrees if done slowly. Complete extension was permitted. There was marked limitation in inward rotation and abduction while external rotation was more free. Two years and twenty-three days after operation she walked easily and painlessly with a slight limp. Flexion over 90 degrees was possible with fairly good inward and outward rotation and abduction. General health good.

The hip bothered her for nine years more or less before operation. For a year she tried hydrotherapy and a flannel spica, and finally came for surgical treatment after having become tired of the slow progress, the incapacity, and after x-rays had demonstrated marked lipping of the upper margin of the acetabulum.

CASE 9. J. S. Well developed man of thirty-one years. Laborer.

At operation the capsule of the right hip was found thickened, and the neck and head of the femur were covered with exostoses which were removed. The head of the femur was denuded of cartilage and squared to fit a shelf made in the acetabulum and solid ankylosis secured in twelve weeks.

Before operation all hip motions were painful and rotation limited very much. Four years and nine months after operation there was solid union in a position of 25 degrees flexion, 10 degrees adduction, and the foot was pointed straight front. He carried no cane and had no pain in the joint.

He came to the hospital with a history of rheumatism, tonsillitis and frequent colds, and x-rays showed hypertrophic changes about the hip joint.

THERAPEUTIC VALUE OF INJECTIONS OF WHOLE BLOOD.

By J. SPENCER DAVIS, M.D., DALLAS, TEXAS.

NUMEROUS articles have appeared in medical literature recommending the use of blood serum in the treatment of various skin diseases, such as psoriasis, pemphigus and the dermatoses of pregnancy.

In some cases the patient's own serum was used while in others it was secured from a second person. In these cases only the serum was used, after being inactivated by heat, but the results of this method of treatment seems to vary greatly in the hands of different observers.

In 1908, Hiss pointed out that the injection of an extract made from leucocytes is capable of producing a leucocytosis. The leucocytic extract was obtained by injecting a mixture of meat broth, starch and aleuronat into the pleural cavity of an animal which is followed by a copious cellular exudate. The leucocytes accumulating in the pleural cavity are removed, mixed with water and kept at incubator temperature until auto-digestion occurs when the extract is put on ice until used. He found that many infections were greatly modified by injections of this extract.

The technic is not so very complicated, but has to be carried out in a laboratory, and besides the yield of leucocytic extract is not very great. Some observers think that the extract thus obtained is not so potential as it might be owing to the fact that the leucocytes are inflammatory leucocytes.

Archibald and Moore attempted to simplify the technic by withdrawing blood from an animal, mixing with a solution of sodium citrate, and separating the white corpuscles by centrifugalization. Further steps for making the extract were similar to that described by Hiss. Leucocytosis produced by this extract occurs very promptly reaching its height in a very few hours, to subside to normal in about 24 hours. The greatest increase is in the polymorphs, while the eosinophile increase ranges from 14 to 45 per cent.

Gay and Claypole under the title of "Specific Hyperleucocytosis," point out that injection of immunized rabbits with typhoid organisms is followed by a marked increase of the leucocytes. They point out that this leucocytosis is specific and only occurs when the animal is vaccinated with the same organism to which it is immune.

In tuberculosis the injection of tuberculin is followed by a similar response on the part of the leucocytes, but the eosinophile increase is, as a rule, relatively greater and more constant than that of any other cells. The leucocytosis produced by tuberculin is specific and does not occur in normal individuals. The repeated injection of any foreign protein produces a leucocytosis.

There seems to be some difference in the len-

cocytosis produced by the injection of foreign proteins and of leucocytic extract made from the animal's own blood. In the former, with a second injection, the eosinophile cells usually are markedly increased; while in the latter, it is the polynuclear variety which has the greater increase. It seems probable that the leucocytosis produced in all the above mentioned conditions is due to the fact that we are either injecting a foreign protein or an extract of a protein.

On the account of the difficulty of obtaining leucocytic extract according to the original method of Hiss we attempted to use an extract made according to Archibald and Moore.

Injections of this extract in normal persons increase the leucocytes a moderate degree, but frequently, in the presence of an infection, it produces no demonstrable effect. With the view of obtaining such a leucocytosis we decided to try the effect of whole blood. This was begun about a year ago. Blood examinations were made before and after the injections. The effect noted on the blood is the same as that produced by injections of leucocytic extract, viz: The leucocytes are rapidly increased, sometimes to 500 or even 600%. The increase reaches its height usually in about six hours, but instead of going back to normal in 24 hours, it is apt to persist for two or three days. The physical condition of the patient also seems to be a factor in the time and the amount of response to the injection.

One of the tables shows a case of diabetes which even after 20 injections of 40 c.c. of blood each time, showed only a very slight increase in the total count. A great many times the height of the leucocytic curve would not be reached in six hours but would be delayed for 12-24 hours. In the presence of infection, the leucocytosis persists even beyond the 24 hours, but occasionally in the presence of severe infection the leucocytosis does not occur until after two or three injections, in which case, the response may be greater than would be expected from a single injection. As a rule eosinophile cells are not so markedly increased as they are in anaphylaxis but the polynuclear cells are practically always increased both absolutely and relatively. Sometimes the polynuclears are increased without any actual increase in the total cell count, in which case the increase in polynuclears is accompanied by a decrease in small lymphocytes. This is not the only effect which is observed. In many cases of infection, a crisis seems to be brought on, the patient having a profuse perspiration and marked fall in temperature. At times it has considerable pain-relieving properties, and is of great value in the treatment of infectious arthritis. The pain is sometimes greatly relieved, even when the leucocytes are not markedly increased, while at other times, even though the leucocytes are enormously increased, pain is not relieved, and the clinical condition of the patient is not improved.

TECHNIC.

Blood is withdrawn by a 20 c. c. Lure-glass syringe attached directly to a "Neo Needle." The needle is introduced into a vein of the arm of the donor and as soon as the syringe is filled with the blood, the Neo Needle is removed and a straight needle applied to the syringe and the blood is injected into the loose tissue of the abdominal wall.

Some experiments were carried out to determine how small a quantity of blood would be effective, and if a greater response could be induced by altering the blood after it had been withdrawn from the donor. The smallest quantity of blood capable of producing a noticeable response was 1 c. c., but in many cases this was not sufficient, and larger quantities had to be injected. The increase in leucocytes is not directly proportionate to the quantity of blood injected, and the injection of a pint of blood was found to produce no greater response than three or four ounces.

Any substance which alters the blood after being withdrawn seems to enhance the effect of the injection. Blood which is kept in the syringe until clotting has begun seems to cause a greater response than if it is injected immediately after withdrawal and before clotting has begun.

Normal saline mixed with the blood to be injected does not seem to be of any assistance, but sodium citrate solution mixed with the blood causes it to produce a greater leucocytic response. A number of other substances were tried, but no marked difference between them and the sodium citrate was noted. The pain-relieving properties seem to have some relation to the quantity of blood injected, but the patient's own blood does not seem to have any marked pain-relieving properties. On several occasions we attempted to use the blood of the patient which was withdrawn and reinjected hypodermically. The response is not nearly so great as when blood is obtained from another individual, but if the blood of the patient is changed by admixture of strong sodium citrate solution the leucocytic increase is very much greater.

The blood used for injection has been kept for several days on ice after the addition of a preservative, without destroying its therapeutic value.

Pain relieved in 24 hours but no marked increase of leucocytes.

MASSAGE AND REMEDIAL EXERCISES IN THE TREATMENT OF CHILDREN'S PARALYSES. THEIR DIFFERENTIATION IN USE.*

BY JENNIE M. COLBY, BOSTON.

Recently Director of the Clinic for Muscle Training of Paralytic Cases, Children's Hospital, Boston.

SINCE, in some types of paralyses the nerves are over-stimulated and in others unresponsive—and in some the muscles are limp and wasted, in others firm and well nourished, it is reasonable to presume a difference in the use of the massage, friction, etc. And since some types lack initiation and others possess normal power of co-ordination that there would be ground for distinguishing between the exercises employed.

* Read before the Massachusetts Therapeutic Massage and Gymnastic Association, Inc., Boston, May 11, 1915.

Results in my own experience seem to justify this view and I differentiate as follows in applying treatment by means of massage and exercises:—

In the anterior-poliomyelitis cases, where the muscles are limp and wasted and the reflexes absent, the aim is to encourage muscular growth and development, therefore I use kneading of the light, rapid, stimulating form, friction, nerve vibration, all gently applied, and in old cases sometimes—but not habitually—percussion. The kneading and friction I apply to the limb as a whole, the vibration and percussion only locally.

In spastic cases, on the other hand, where the muscles are firm and well nourished and the reflexes exaggerated, I quite reverse my choice of procedures, omitting entirely friction, vibration and percussion, and using kneading in a modi-

fied form, viz., applying it with the palm of the hand, using deep pressure and slow movement for the limb as a whole, but being watchful to avoid producing reflex contractions. In the obstetrical arm, conditions in the early stages—usually for the first year—resemble those in poliomyelitis, and the same forms of treatment are applicable,—gentle kneading, friction and nerve vibration—the kneading and friction for the arm as a whole.

As the patient improves the movements can be increased in force and duration until they become the usual form for stimulating muscular development.

In old cases—children of several years—I begin, at once, with the routine massage, friction, vibration and percussion, such as I might use with any old traumatic case.

Passive movements of the joints for these paralytic cases are given for the purpose of keeping the surfaces of the joints in their proper relation to each other. In all old cases in each type there are sure to be more or less deformities, and then each case and each joint becomes a law unto itself. In the early stages of poliomyelitis and obstetrical paralysis there is a tendency to relaxation of the joints, and, therefore, I feel that it is safer to keep the movements well within the normal range of motion.

I believe that the anterior poliomyelitis type tends to relax whether left to itself or under treatment.

The obstetrical arm (peripheral) steadily improves in this respect, and after a few months will tolerate and even require hyper-extension. To avoid dislocations and yet not allow adhesions to form is a perplexing problem.

For the spastics it is difficult to generalize on the use of passive movements. The cases are invariably old cases when they are presented for treatment, and have deformities which must be considered individually. Frequently, where there are no visible deformities and the overlying tissues seem firm and elastic, there will be an apparent separation of the bony surfaces, which makes it seem unwise to force movement as far as the contracting muscles would indicate. Sometimes the grasp of the operator will aggravate the spasm. Often here and elsewhere the passive movement must be more or less of an assistive movement in order to prevent resistance on the part of the patient.

The question of stretching contractures is really outside the topic of "passive movements of the joints." It often happens that the joint is used as fulcrum with the distal portion of the limb as lever, but it is not always safe, and the exact condition of the joint must be considered before so using it. Sometimes it is better to stretch the tendon between the hands of the operator—when there are true contractures. If the joint is used for the purpose of stretching muscles which are attached to one or another of its surfaces, it must first be so fixed that it cannot move in any other than the desired direction

of motion, and the muscle, or the contracted portion of it, must be pulled in line with its median fibers.

The active exercises offer the largest field for differentiation in applying treatment to these paralytic cases. The poliomyelitis cases need exercises to develop muscular tone rather than coördination of movement. The spastics need those which cultivate control rather than strength of muscle. The obstetrical arm requires both types, but for other reasons.

In treating the poliomyelitis cases I like to use the assistive form of the active exercises, because in this condition the patient apparently sends the first impulse unerringly to the muscle which it tries to move, and if the muscle responds the relationship continues, but if the muscle fails to respond, the effort is automatically and instantly transferred to some adjacent muscle. If, however, the limb is held in an advantageous position, and the first impulse aided to perform the intended movement, the impulse is not as readily diverted, and seems to continue to act upon the right muscle until fatigue occurs. The fatigue can also be detected more quickly through the use of the assistive movement before it becomes exhaustion or the effort is transferred to other muscles. The instant that I feel any sort of *flagging* I usually tell the patient that he need not try any more, but I go on with the passive form of the movement, and frequently I feel the impulse again at work of its own accord. Even when the patient has the strength to make a few contractions alone or to overcome some resistance, I still prefer the assistive form of exercises for treatment purposes. This method saves putting a relaxed joint into hyper-extension for the beginning of the movement, and proportionately more movements can be used without causing fatigue, on the principle that a larger number of light movements equals a smaller number of heavy ones. The assistive exercises also act more normally upon the antagonists and afford the most convenient way of teaching very little children.

I use very few free gymnastics in these poliomyelitis cases,—a little walking, running and dancing, a little practice on the balance-beam, the Sequin ladder and the stairs, but only in order to teach the proper form of doing such things as the patients are attempting of their own accord, not as exercise drill.

For the spastic cases the voluntary coördinatory exercises constitute the most important part of treatment. The aim of the exercises is to develop control of direction, localization and amount of effort put forth. As coördinatory exercises, they should not be of the assistive form except in order to describe the movement. They should be of great variety, of both general and special character.

In addition to the numberless formal gymnastic exercises, all sorts of everyday activities should be employed, e.g. for hands and fingers, buttoning clothes, lacing and tying shoe strings,

braiding hair and picking up articles from the floor or table and placing in a receptacle carried in the healthy hand, and so on indefinitely.

Simultaneous movements for arms, hands and fingers of both sides (paralyzed and normal) are of special value. Besides the regulation "symmetrical gymnastic exercises," the piano, peg board, blocks, crayons, etc., can be utilized. Useful exercises for the lower extremities are stepping over and upon objects, walking in a variety of different ways, dancing, sliding on bare floors, skipping rope, and when safe, skating, climbing and riding velocipede or tricycle.

Even when the muscles are more or less constantly in spasmodic contraction the voluntary form of contraction is desirable because exercising control over the movement reduces the spasmodic activity. The voluntary exercise should be carried to a point beyond that usually maintained by the spasm. Special exercises for the antagonists are obviously in order.

For the obstetrical arm all types and forms of exercises are needed at one time or another. During the first few weeks of life they are necessarily passive movements of the arm as a whole in imitation of the bendings and stretchings instinctively performed by its mate. Later these passive movements merge into assistive movements and the assistance is withdrawn as soon as the child has the strength and knowledge to perform the movements alone. From three months onward exercises demanding attention are important, not for the purpose of cultivating coördination, as with the spastic cases, but to arouse delayed association between the mind and that particular limb, and to localize movements for the purpose of muscular development. After three years of age, exercises for the obstetrical arm may be the regulation gymnastic arm exercises or "shoulder-blade movements," and with the addition of exercises for developing skill of hand and fingers if needed. Attention must be given to the peculiar needs of the individual. To secure exercises of attention from babies and young children requires resort to some aspect of play,—“play educates the baby,” and educates the young of the dumb animals, and can and must, in order to procure the most satisfactory results, be used in applying reeducational exercises to little folks. For the tiny baby I have followed the universal custom of attaching rhymes to movements of the body: “Pat-a-cake” for the hands, “thumbkins,” etc., for movements of the fingers, “measuring” for the arms, “shoe the old horse,” “this little pig goes to market,” and so on, with numerous “mother-plays” and “finger-plays.” With older, but still little, children I have used the gymnastic movements the effect of which I desired, under some name or with some jingle which appealed to the child’s imagination: “See-saw” for arm abduction, “Jack-in-the-box” for knee flexion, etc. Many of these are described in Miss Johnson’s and my little book, “Educational Gymnastic Play,” and some of the baby exercises

which I wrote out for Dr. Thomas are published in his article on “Obstetrical Paralysis with Especial Reference to Treatment.”

Daily occupations can be used as therapeutic exercises, if carefully chosen,—stirring, grinding, weaving, sewing, pounding, digging, etc. Certain toys are also useful, such as a wheelbarrow, toy tether ball and racket, jumping-jack on a string, and many another.

Games of various sorts readily lend themselves to use as remedial exercises, but to be truly re-educational they must be adapted to the special needs of the case and the individual. The scientific gymnastic movement should be the foundation for the exercise play.

The question of home treatment and activities often comes up. I feel that it is advisable for the poliomyelitis cases to have some gentle massage and friction at home, if there is any one who can do the manipulating tolerably,—briefly, fifteen or twenty minutes only at one time. The person giving the massage should be warned against holding the limb in a position which will stretch relaxed ligaments or increase deformities while giving the treatment. For the spastic cases I say no massage or friction at home and for the infant obstetrical arm, little, if any, and very cautiously, given during the first few months; after six months or a year I have allowed it, but not required it.

For the home exercises I reverse the order,—practically none for the poliomyelitis cases, for the spastics many and varied, for the infant obstetrics very gentle movements at first, many arm activities later.

The poliomyelitis cases, in my opinion, should not be urged to use the affected limb except when assisted. They will do more than they ought of their own accord. The child should have a rest of at least an hour a day, lying flat upon the bed or floor, with relief from all activity of the weak muscles and the drag upon relaxed ligaments.

Since I have acted upon the principle of holding back the recent poliomyelitis cases, I have seen much less deformity in my patients of this class. It requires considerable care to give a child enough normal activity without producing fatigue and deformity, but I feel convinced that for the first one or two years it is distinctly worth while to make the effort.

When the lower limbs are affected, chairs should be low enough, or provided with foot-rests, to allow the feet to rest flatly, with the knees at right angles and kept from separating. Tables of corresponding height should be supplied. If there is toe-drop, a strap fastened at the toe of the shoe and caught in at the top with the lacing, will keep the child from stubbing its toe and prevent the swinging at the hip, which is so likely to bring on deformity. If the shoe strings of the two shoes are tied together, giving just room for a natural length of step, the child is less likely to walk with stride-gait. The arm is sometimes best kept in a sling at intervals.

The spastic patient should have a great deal of home exercise, should be encouraged to join in the play of the other children, and the activities of the home. The majority of these patients need constant urging, as they are not inclined to use the affected limbs spontaneously. The exact performance of the movement in these cases is of less importance than the effort made, and so the exercises are more easily directed by the mother or other members of the family.

The obstetrical arm patients as infants are often too loose jointed to permit of unskilled handling, but as soon as the joint becomes firm enough to be in no danger of dislocation, the arm should be exercised by the mother, and the baby taught day by day that the paralyzed arm must do whatever the other arm does. Week by week and month by month this teaching constitutes the principal part of the home exercise—the other arm being the guide for progression. The little gymnastic exercises arranged for both arms and associated with some nursery rhyme have a certain value, and the mother usually learns them readily, and applies them with the necessary enthusiasm for holding the child's attention. As with the spastic cases, there must be constant vigilance in having the child use the arm in its play and work year after year if a perfect recovery is sought. The task is, however, far easier than with the other types, because there is less danger of over-doing and but little of wrong-doing. Less watchfulness is required with the obstetric than with the poliomyelitis subjects, and while, like the spastics they need continual urging, there is usually but one limb to consider, and only a few definite movements to require. As the disinclination to use the arm is inattention, rather than true incoördination, it is also more readily overcome.

As regards fatigue: the poliomyelitis patient is easily exhausted, even when the ease is of long standing, and should always be protected against overdoing. The spastic patient is not so susceptible to fatigue, but the fatigue should be avoided as a cause of discouragement, if not as a physical harm. The obstetrical arm subject needs consideration only in regard to age—the tiny baby must be guarded very carefully, the ten-year-old child may be allowed normal activity.

The frequency of treatment must be governed by circumstances. The interval can be shorter when the child is visited at its home than when it has to be carried to an office or hospital.

Short treatments daily by the skilled operator for the first two years would be ideal.—three times a week gives very good results, twice a week will accomplish something. Less than twice a week I do not care to consider.

Treatment should continue as long as the child responds to it, with occasional interruptions after the second year.

JOSEPH FRANÇOIS MALGAIGNE, 1806-1865.

By WM. PEARCE COUES, M.D., BOSTON.

AMONG that galaxy of surgical stars which shone on the horizon of France during the early part of the nineteenth century, none are more justly famous than Malgaigne. Perhaps the times of stress and terror through which France had just passed had something to do with the production of men of such indomitable will and determination as that possessed by the subject of this sketch. Most of the surgeons of note in France at this time rose to eminence after toils and privations almost unbelievable at the present time; the love of their profession was so great that nothing could turn them from the distant and arduous goal of their ambitions. When we seek to analyze the character of such men certain facts stand out distinctly. Seemingly common to all, we find a capacity for work and a power to overcome obstacles rarely met with at present. It seems doubtful if many of the great surgeons of the present day could put up with the hardships, privations, and often in the earlier years, actual want of some of the necessities of life, and still keep the eternal fires of genius burning bright. Thus we find Velpeau in his early years, living in Paris on nine sous a day. Fortunately for him and his art, this direful state of affairs did not last a long time. A consideration of the medical training of such men as these brings out another fact, that is, the wonderful grasp of the science of medicine as a whole that was attained in conjunction with the study of surgery. This would be a great aid to many surgeons of the present day; often too prone to fly to the internist for advice concerning matters which it should be their duty to know.

Joseph François Malgaigne was born at Charmes, department of the Vosges, on February 14th, 1806. His father also was a physician, being an officer of health of Charmes and also attached to the sixth regiment of foot artillery. Originally the family was of Italian ancestry, and there was noble blood from the mother's side of the family. The Malgaignes were not endowed with any considerable quantity of worldly goods, and the father's ambition was to have his son obtain a position as health officer similar to his own. This, however, did not by any means satisfy the young man's ambitions and led to a family disagreement later. Young Joseph went to Nancy for the first part of his medical education. From here he writes home a long and entertaining letter concerning his studies, which were rigorous in the extreme; in his enthusiasm and descriptions in this letter we get a hint of what his future accomplishments in medicine might well be. At nineteen years of age he obtained the title of officer of health, but this was not what he wished for in medical attainments, and his determination to go to Paris

to seek wider fields of endeavor and opportunity caused a serious breach with his family. Pilastre tells us that during the youth's early days in Paris he lived on 85 centimes a day and worked in bed on account of the intense cold, not having enough money to buy fuel to heat his poor room. He prepared his own meagre fare and suffered extremely. He managed, however, to earn a small amount by teaching anatomy, and began writing articles for the journals. In 1826 he was chosen a student in the "Ecole Pratique," one of the two great schools of dissection in Paris at that time, with which Velpeau and Cloquet were connected. In 1827 he became externe of the hospitals, and obtained a prize for his dissertation, "Nouvelle Theorie de la Voix Humaine." He finished his medical training at Val-de-Grace, the military training school, where he obtained a prize which gave him the right of residence in a military hospital.

Soon after this we find him working for stricken and harried Poland. He was attached to the fourth division of infantry, and organized an ambulance of twelve surgeons, which was of the greatest service to the country. Many jealousies and other difficulties had to be overcome, engendered by the attitude of the Polish physicians, before success was obtained. On finishing his work in Poland he returned to Paris and published a memoir entitled "Coup d'Oeil sur la Médecine et la Chirurgie en Pologne."

In 1835 he was made "Professeur Agrégé," and was attached to the celebrated St. Louis and to the Charité. Malgaigne was an accomplished orator, and all his discussions and sayings at the Academy were followed with the keenest interest. Like all great men who have new thoughts and procedures, he had enemies and detractors. It has been said that so keen was his power of oratory that, had he taken up the law instead of medicine he would have been equally successful. During his first struggles in Paris he would repeat, "Patience! the future is long, and it is mine; I will live or die in Paris!" Malgaigne understood the real value of surgical operations; and he was probably the original end result surgeon, saying it was necessary to follow up the surgical cases, to see them at a distant time, and note what deformities or what inconveniences had resulted from operation. In his thesis, written when he was 25 years old, he said, "We have no history of medicine," and again, "Any man, even a genius, who does not see and work for the time beyond his own in medicine, resembles a dotard, living only in each day." Some of Malgaigne's best known works are: "Letters on the History of Surgery," "Anatomy and Physiology of Homer's Times," "Greek Medicine, before Hippocrates," and the "Works of Ambrose Paré." Malgaigne was the first surgeon in France to use ether for general anesthesia; he also was the first to use collodion in surgical work. He

introduced sub-hyoid laryngotomy, first performing it on animals. His many works on fractures were, and still are, authoritative on many points. Perhaps his greatest work, his "Manuel de Médecine Opératoire," was translated into German, English, Russian, Italian, Arabic, and seven editions went around the world. Malgaigne was the author of biographies of Astley Cooper Boyer and Dupuytren; and Pilastre, in speaking of these works, says that they are interesting, not only for the lifelike depiction of the characters studied, but also for the picture they gave of medical science of the times apart from this. In his biography of Cooper, Malgaigne tells the following story: In 1820 Cooper was consulted by King George IV, and in 1821 was asked to remove a wen from the head of the august patient. Cooper was very loath to accept the responsibility thrust upon him and begged Lord Liverpool to persuade the King that Hane was the surgeon to operate, as he was by title Surgeon to the King. Cooper dreaded the occurrence of erysipelas after the operation and that such an occurrence would blast his reputation, as it very likely would have done. He said, "The announcement that I was to operate on the King brought on an attack of vertigo; I felt that my whole future depended upon the result of this operation." The operation was successful despite his fears, and Malgaigne tells us that Cooper was given a present of five hundred guineas, receiving the title, of Baronet, and in 1824 was named Surgeon to the King.

Among the personal anecdotes of Malgaigne the story of his controversy with Count de Bernstorff, as related by Pilastre, is of interest. Bernstorff was at that time Prussian Minister to France, and had consulted Malgaigne concerning his health and that of his son. After several visits and consultations on the part of Malgaigne, a servant of the Count appeared at the surgeon's residence with an envelope containing fifty francs, for which he demanded a receipt. Malgaigne, returning shortly, summoned his servant, and dispatched him with the following note to the Count:—

"I have the honour to send to Monsieur Count de Bernstorff, Minister of Prussia, fifty francs which have been left at my house from him. I am sovereign in my art; and it is necessary to observe certain forms with me.

"I beg of you at the same time, M. le Count de Bernstorff, not to mention my name to M. Lawrence, to whom probably a similar alms sent in a similar manner would be no more acceptable.

"Malgaigne.

"29 November, 1855."

Soon after this note was dispatched Malgaigne received a charming note from the Countess de Bernstorff, full of regret and chagrin at the occurrence, which was acknowledged by the surgeon in a graceful note, such a note as only the French can write. The Count called soon

after, but Malgaigne would never accept payment for his services.

Part of Malgaigne's great work was his introduction to the works of Ambrose Paré, which was in itself a complete work on the history of surgery from the Sixth to the Sixteenth Century. This comprised fourteen chapters, beginning with Surgery of the Orient in the Sixth Century and ending with a description of French Surgery in the Fifteenth Century. There was also a special description of the military surgery of the times and the military campaigns. This work placed Malgaigne among the first rank of medical historians of all time.

One of the most interesting events in his career was his controversy with Jules Guérin, the orthopedist, whose results, case reports, and theories were the subject of bitter attack by Velpeau, Malgaigne and other French surgeons of note. Pilastre gives the following interesting facts concerning this historic medical controversy and law suit on the part of Guérin against Malgaigne and Vidal (de Cassis). Guérin was a pioneer in orthopedic surgery, and his editorship of the *Gazette Médicale*, which he held all his life, gave him a wonderful opportunity to put his views before the medical world. He devoted himself passionately to this work, but unfortunately did not always use the tact necessary in giving forth his views. He had obtained in 1837 the Grand Prix offered by the Academy of Sciences by a work entitled: "Détermination Scientifiquement Rigoureuse des Principes Methodes et Procédes de l'Orthopedie; Sous le Double Rapport de la Pratique et de la Theorie." Perhaps his critics thought that this title "Doth protest too much"; at all events, his views were continually challenged, as is always the case with new theories, and practical application of them, be they good or bad. Guérin was one of those who bitterly opposed Pasteur's theories of the microbic origin of disease. In 1843 began the great controversy with the Paris surgeons in which Malgaigne took such a prominent part. He had combated the views of Guérin in the *Journal de Chirurgie*; here he contested the so-called operative cures of Guérin, saying that the dignity and the morality of the art of surgery was at stake. As a culmination to all this Guérin brought his suit against two of the signers of a letter of protestation against his work and methods. The suit was for defamation and injury, to the amount of 20,000 francs: the trial was held November 14, 1843, all medical Paris, as well as crowds of the laity being present. Malgaigne was acquitted of any culpability in the matter. Unfortunately for the side of free medical criticism, the others Vidal (de Cassis) and Henroz were not so fortunate. Notwithstanding this, the medical profession, as a whole, regarded the trial as a victory for free speech and criticism in medicine.

For a time we find that Malgaigne was interested in political life, being a member of the Chamber of Deputies, but in 1848 he gave this

up and the rest of his life was entirely given over to his medical work.

The manner in which he became a member of the Chamber is as unusual as it is interesting. In the midst of some medical literary work, nothing was farther from Malgaigne's thoughts than politics, when he received a circular of a political meeting urging his presence for the purpose of voting for a new deputy in his district. Malgaigne felt it his duty to go to the meeting. On arriving at the hall he found no one he knew, but after a time two pharmacists who knew him by reputation addressed him. Soon he was surprised to see an officer of the meeting hurrying toward him. He came to ask if Malgaigne would not act as president of the meeting, as there was no one present who could do it as well as the accomplished physician. There were two candidates to be considered, one of whom did not come to the meeting, so that Malgaigne counselled another meeting to give the other candidate one more chance. This seemed to meet the approval of the meeting, and when Malgaigne dissolved the assembly there were many expressions of approval of his conduct of it. Entirely because of his presence at this meeting, and his subsequent popularity among those present, he was himself elected deputy of the fourth arrondissement in 1847. He was a member of various commissions, which had the consideration of questions of medicine, hygiene, and public instruction. The work that Malgaigne did was most valuable, but he could not give up a long time to such political commission activities, and was not a candidate for re-election, plunging again into his surgical work and medical writing.

The 10th of January, 1865, while presiding at a meeting at the Academy of Medicine, he was stricken with apoplexy, and lived only for a few months after this time. Velpeau, in his eulogy of his former pupil and late colleague, said that he considered that Malgaigne was the greatest figure in the science of the times. His labors, Velpeau said, were immense, almost unbelievable. Pilastre ends his interesting account of Malgaigne with the following quotation from Voltaire concerning physicians, taken from the "Dictionnaire Philosophique." The first part of the quotation holds up to ridicule the same type of physician as Molière satirized, but then goes on to say: "It is none the less true that a good physician may be able to save our lives on a hundred occasions, and to give us back the use of our limbs. A man falls in an apoplexy, and it isn't a captain of infantry or a councillor who will cure him. Cataracts form in our eyes; my neighbour won't remove them. I make no distinction here between the physician and the surgeon; these two professions have been for a long time inseparable. The men who seek to give back health to other men, using the principles of humanity and well doing, are really much above all the greatest and most powerful of the earth. They have something of divinity

about them. To conserve and repair is almost as beautiful as to create." Such a tribute to medicine from the cynic of cynics is high praise, indeed, but well merited by such a master mind of surgery as that of Malgaigne.

A SUCCESSFUL TREATMENT FOR ACUTE INFECTIONS OF THE AIR-WAYS.

By IRVING WILSON VOORHEES, M.S., M.D., NEW YORK.

Adjunct Professor, Fordham University.

ANY acute infection of the respiratory tract, whether it be "in the head" or "on the chest" is conveniently described by the layman as "a cold." Perhaps, now that custom seems to have justified the usage, this is as good a general term as any other. After all, it is not the word, but the *thing*, with which we must concern ourselves.

It is a common observation in esoteric circles that "a cold must run its course." If the truth must be told, there is ground for a lurking suspicion that the profession has not hotly contested this assertion. A well-known professor of therapeutics was once heard to tell his class that "the public does not come to us any longer to be relieved of a cold because it knows that we cannot cure this annoying condition." The profession is now very sure that a cold is something more than an annoyance. It is a real danger, because it may have as a cause the diplococcus of pneumonia or the bacillus of tuberculosis, masked by the micrococcus catarrhalis. A cold is an acute infectious disease and should never be neglected. If its tendency to spread were widely understood, it would doubtless become one of the reportable diseases set down in the Board of Health lists along with scarlet fever and diphtheria. To be sure, most people recover from a simple rhinitis or laryngitis or bronchitis, but who can say that these do not furnish the soil and lay the stratum for many other diseases, both acute and chronic? Have we not, as physicians, been negligent in studying the bacteriology of the secretions in rhinitis and bronchitis? Have we consistently tried to shorten the course of these air-borne infections, or have we made any concerted effort to check their spread? The Commissioner of Health for Greater New York City, Dr. S. S. Goldwater, ought to be heartily supported in his efforts to prevent droplet infection in public conveyances. It may be an impossible task, but it is worth trying. Perpetual warfare ought to be waged against the universal ignorance of those who cough and sneeze in public places without protecting the face with a handkerchief. Spitting on the floor, while disgusting, is in reality much less dangerous to the public health, than this sputtering of fresh germ-laden spray into the air-ways of the defenseless passengers. The pervading odor after a sneeze gives a vivid

representation of the great number of persons who can be infected from one source alone. No wonder that an entire audience may "get a fit of it" after some thoughtless person has sprayed the entire atmosphere. When the light is properly placed, as, for instance, in a direct ray of sunshine, a veritable shower of spray after a sneeze may be seen to disseminate itself in all directions. It is a momentous fact that almost all of the acute infectious diseases of childhood—scarlet fever, measles, diphtheria, etc.—first manifest themselves as mucous membrane diseases by acute catarrhal symptoms from the nose, watery eyes, or plaques, patches and spots in the mouth and pharynx.

When a cold is once under way what can be done to shorten its course or to prevent its spread to others? Many authors have written widely (perhaps more widely than wisely) on this subject, most of them from the general standpoint of internal medication—the use of quinine, belladonna, calomel, etc. When studies of nose and throat conditions, as special entities, had their first great beginnings a promising forward step was taken. Unfortunately, however, much of the local treatment has consisted of sprays and inhalations. These, while of undoubted value, are not sufficiently concentrated, or of sufficient strength, to be markedly bactericidal. As a result of the physician's lack of interest or inability to produce results, self-medication at home has become widely prevalent. Such medication is often due to the tender consideration of an obliging druggist, who feels in duty bound to placate a customer by handing over the counter various drugs, such as quinine, aspirin, salol, phenacetin, rhinitis tablets, troches, lozenges, etc. If a cough becomes so severe as to disturb markedly the course of a patient's daily life some compound cough mixture is taken. This upsets the stomach, and the last state of such a man is worse than the first. There is no doubt that constitutional treatment must often be combined with local measures, but not in the majority of cases, for just so soon as the local condition is improved general symptoms quickly clear up. Now it would seem that the logical method of treatment is not to administer drugs by stomach, if drugs are to be used at all, but to apply such remedies directly to the site where action is desired, that is, into the nose in acute rhinitis, or into the pharynx, larynx, and bronchi when these parts are the location of active inflammation. In any case, much depends upon the germ with which we have to do. We must not forget that vaccines are also sometimes indicated when the predominating germ can be isolated.

In dealing locally with acute infections in singers, the two remedies most commonly used by specialists are silver in some form or iodiform. The silver salts are all irritating when used strong enough to be efficacious. Many patients object strenuously to having these preparations introduced into the larynx, and not

without reason. Iodoform, in ether or in oil, is a rather powerful antiseptic, but is likewise irritating, and its persistent, unpleasant odor on the breath and in the clothing is a great disadvantage.

During the past three years I have been using, with remarkable results, the well-known aromatic principles,—oil of cloves, oil of cinnamon, thymol, eucalyptol and menthol, not in spray form, but applied directly to mucous surfaces. The physiologic actions of these are commonly set down in text-books as analgesic, anesthetic, stimulant, carminative and bactericidal. They have all been used by rhinologists for many years, but not in a way to derive most benefit from them. Knowing how active these agents are, I began to use them in cases of acute inflammation of the upper air-ways.

My first patient came in at five p.m. on a winter afternoon, absolutely aphonic, almost panic-stricken with fear that she would be unable to keep her engagement for the following night in an operatic part which makes great demands upon the voice. She was told how impossible it would be for her to sing, but argument was of no avail. She "simply must go on." She objected strenuously to the ordinary forms of treatment and asked if there was not something else which might be used. I thought of the possibilities of menthol-oil, and asked if she would like to have it tried. To this she assented. After thoroughly spraying a 2% sol. of cocaine into the pharynx and larynx, about 1 c.c. of a 10% solution of menthol in sterile liquid petrolatum was instilled into the trachea. There was considerable reaction for a few moments, after which a cooling effect was experienced, with great immediate relief of the cough. On the following morning the patient could speak aloud in half voice. Another injection was then given, followed by a third about seven hours later. To my surprise, the patient was able to take her part by a process of "singing over" her difficulty,—a procedure, by the way, which should always be discouraged, as it may do permanent harm to the voice.

Since that time I have used instillations of menthol in oil, 5 to 25%, in all such cases. Not more than five such treatments are ordinarily necessary. One is given in the morning, one at night, at intervals of from eight to twelve hours. Some patients complain rather bitterly of burning. In such cases a few drops of a 10% cocaine solution should be instilled first, followed in a few minutes by the menthol-oil preparation.

In acute bronchitis it is astonishing how effective this treatment may be. Its analgesic action relieves the cough, its stimulant action increases expectoration, its carminative action produces hyperemia, and, finally, its bactericidal action makes it a satisfactory germ destroyer. The oily vehicle is of especial value in soothing an irritated mucous membrane. Treated in this way, a case of simple acute bronchitis, not due

to the pneumococcus or streptococcus, should not last more than 72 hours.

It is of the greatest importance that the instillations should be carefully and accurately placed.

If there is any tendency to gag or vomit the oro- and laryngo-pharynx should be sufficiently anesthetized to reduce all reflexes to a minimum. In acute laryngitis with swelling, redness and exudation from the false and true cords the drops should fall directly on the rima glottidis during phonation. If it is desirable to reach the trachea and bronchi directly, as in sub-glottic infections—tracheitis and bronchitis—the patient is asked to exhale through the mouth. At this moment the patient holds his tongue with a bit of gauze in the right hand, while the specialist uses a laryngoscope with his left hand, the right holding the laryngeal syringe. As soon as exhalation is well under way the dropping is begun, and the patient is asked to inhale through the mouth. This opens the larynx quickly and a good quantity of the medication is taken deeply into the bronchi.

As for the syringe, I prefer the glass laryngeal model commonly used in the clinics of Vienna and Berlin. Unfortunately, however, these are likely to be broken in sterilization. The best syringe I have seen thus far is the Record, which is imported by G. Tiemann and Company of New York City, but it is very expensive. I am now using an all-metal 10 cc. syringe, which is very serviceable, but has the disadvantage of not allowing the contents to be seen. Unless one is very careful, air will get in while filling the syringe, and the sputtering during instillation becomes very troublesome in securing accuracy of placement. It is well to have one or more extra cannulas to save time while sterilizing those already used. In any case a steady hand and a practised eye are necessary, for, if the cannula touches any part of the larynx, or if the drops fall in undesirable areas, violent coughing will ensue and most of the good effect will be lost. About one to two c.c. are usually quite sufficient, but more can be used with impunity, as the treatment is absolutely harmless.

These applications, as already mentioned, should be made at least twice daily, or, in bad cases, three times. The effect lasts for from two to three hours. At first there is a pungent, irritating sensation that sometimes frightens the patient, leading him to believe that acid or some very irritating drug has been put into the larynx by mistake. It is important, therefore, to explain beforehand, just what is likely to take place. Coughing is likely to be rather violent for a few minutes, until the air breathed in begins to aid in the evaporation of the menthol. The secondary effect then begins, and there is a cooling, "open" sensation—a feeling of freedom and well-being.

In acute rhinitis the patient is asked to lie down with the head far extended over the edge of a couch, and the drops (usually a five per

(cent. solution is preferable) are instilled into the nose with a dropper, care being taken to point the dropper upward in the direction of the eyes. This provides for the thorough distribution of the preparation over the mucous membrane surface, before it falls into the throat. Naturally if the nose is swollen shut, it must be sprayed first with a cocaine-adrenalin solution in order to shrink the erectile tissue, otherwise the oily preparation will not pass in.

In pharyngitis one should apply the menthol-oil solution by means of a post-nasal applicator in the usual manner. It is important here that no force be used, but the applicator should be moved from side to side as much as possible in order to distribute the drug over the entire post-nasal surface.

I have found the drops also of use in earache when such a remedy is indicated. In furunculosis, the canal can be packed with a strip of gauze soaked in a 10% menthol-oil solution. This will keep the walls of the canal separated and will help the pain and inflammation, especially in the first stage of the condition, or after pus has been evacuated and it is desirable to keep something in the canal.

Thus far I have used this treatment up to 30% strength in two cases of incipient pulmonary tuberculosis. Relief has been marked, and the number of staphylococci and streptococci has been greatly reduced. There seems, however, to have been little effect on the tubercle bacillus itself. After each instillation the patient lies on the affected side for five minutes to aid in placing the drops where their presence is most desired. It is, of course, still too soon to determine any lasting value from the use of this preparation in pulmonary tuberculosis.

CONCLUSIONS.

1. The course of acute respiratory diseases can be greatly shortened by direct instillations of aromatic drugs.
2. Of these a solution of menthol in oil is most effectual.
3. In many cases the quick result is striking.
4. The procedure is absolutely harmless.
5. It is of the highest value in treating the throats of professional singers.

HEALTH DAY IN CLEVELAND.—The twenty-fifth of October was celebrated in Cleveland, Ohio, as "health day." Pamphlets containing rules of health and information regarding prevention of disease were distributed by the municipal authorities. Moving picture theatres, newspapers and other publicity agencies co-operated and the results appeared so satisfactory that it is expected that a day will be set aside annually for such a celebration, not only in the city but for the entire state.

Clinical Department.

STUDIES IN SPEECH DISORDER.

No. 2.*

PROGRESSIVE MUSCULAR ATROPHY—CASE AND TREATMENT.

BY WALTER B. SWIFT, M.D., BOSTON,

In Charge of Voice Clinic, Boston State Hospital, Psychopathic Department; Instructor in Neuropathology, Tufts Medical School.

ABSTRACT I.—RARE CASE, USUALLY NOT CONSIDERED TREATABLE. II.—SHOWN TO BE P. M. A. III.—IMMEDIATE RELIEF.

AN interesting case called upon the Voice Clinic for help in speaking and relief from an annoying and rather unusual affection of the throat musculature. The case is of interest in two ways: (a) it is one generally considered not amenable to treatment, and (b) it is an illustration of the extreme variety of lesion which merely from a defect of speech are brought to this clinic.

It also sets an example to those dealing with speech defect to exercise their ingenuity in every effort to try to relieve these too often considered incurable cases—even when but slight relief is possible—without permanent cure. Usually such cases go untreated—and many of them when marked relief is possible. Witness the stutter treatment of a few years ago; witness the occasional expulsion from school for mere speech defect; witness the years of delay in education that even some slight speech inability—the often easily cured case—imposed upon the young quite needlessly. Such truths lead us to look upon the relief of speech defect as no small matter, and it justifies the many years of study needed in this subject in all its phases—muscle, nerve, brain and function and the educational side—and give ground for a righteous indignation against the "incompetents" who dare enter the field only one-sidedly prepared.

Let me present the case and discuss the treatment afterwards:—

CASE: Man, 51, Irish cooper. Complaint: Weakness of leg and indistinct speech.

Present Illness. Began at night ten months ago with sudden cramp in his right leg. Soon the foot and ankle became weak. About seven months later indistinctness of speech came on gradually. Not now growing any worse. Weakness of legs increasing. Has left work for two weeks on account of it.

Past History. Measles as a boy. Influenza at 36. Otherwise never ill.

Family History. Grandparents unknown. Father died 75, cancer. Mother died 52, tuberculosis. No history of speech defect.

* No. 1 of this Series appeared in the BOSTON MED. AND SURG. JOUR., January 30, 1913.

Physical Examination. Well developed and nourished. Middle-aged man. Pupils regular and react to light and distance. Throat: Tonsils not enlarged, not reddened. Glands in neck are normal. Chest, heart, abdomen negative. Liver, spleen not felt. Genitalia, left hydrocele size of a large orange. Right leg atrophied, $\frac{1}{2}$ inch smaller in calf and $\frac{3}{4}$ inch smaller in thigh. Reflexes: Knee jerks present on both sides, much more markedly on the left. No Babinski. Ankle jerk present on the left. Absent on right. Wassermann is negative.

Vocal Record. Complaint, indistinct speech.

Present Illness. He first noticed inability to swallow about three months ago accompanied by regurgitation. This has persisted since. Six weeks after the onset he noticed indistinctness of speech. It varies somewhat, but is never normal.

Vocal Examination. "Baby" is said with a nasal twang and an over-amount of pharyngeal resonance. "Today" is uttered with correct T, but also evidence of lack in pharyngeal support. "Nobody knows how," said very easily without attempt at throat contraction. "Good going" said with great effort, marked throat resonance and slightly faulty explosives.

Diagnosis. Progressive muscular atrophy. Atrophic extension into muscles of larynx. Vocal laryngeal non-support.

The problem here presented is how to relieve a case of atrophy in the throat musculature so that clear expression would result. To expect anything from atrophic muscle directly is hopeless. Medication—strychnia—is sometimes used with slight show of improvement. To make the sounds clearly that demand exact muscle action the muscles must be enervated, must contract and reach by such contraction exactly determined points and positions demanded in vocal utterance.

The case under discussion showed nerve enervation present and some action, yet not the far reached action needed for the tone execution sought—yet enough and in such form as to make the end result perfect if only the intermediary step could be helped out. It, therefore, seemed that *laryngeal support* would do it. I, therefore, proceeded to train my atrophic patient to support his throat musculature with a certain definite position of his hand. Immediate results followed. I mean no permanent cure, but merely the sounds came at once clearly and easily. This continued as long as the support was present and, of course, vanished without it. But even with palliative relief, considerable help was rendered in enabling the patient, to make people understand him easily. The patient agreed that the trouble taken was well repaid by the complete relief, though temporary, that the patient was thereby enabled to apply thereafter. A special collar could have served the same purpose, or sometimes bending the head forward and resting the anterior neck upon a high standing collar served as well.

Summary. Case of progressive muscular atrophy with involvement of muscles of the neck to such an extent as to render some sounds impossible and others indistinct, is relieved at once, and afterwards whenever applied, by giving

the throat musculature staunch, firm support by hand, special collar or high collar applied to help out the action of those neck muscles.

A CASE OF THROMBOPHLEBITIS OF THE VEINS OF THE CORD ASSOCIATED WITH COLON BACILLUS INFECTION OF THE EPIDIDYMIS.

BY E. GRANVILLE CRABTREE, M.D., BOSTON,

Resident Surgeon to the Genito-Urinary Service of the Massachusetts General Hospital; Fellow in Surgery in the Harvard Medical School.

THE history, pathological, and bacteriological findings in the case about to be described are of interest because they illustrate a group of cases of cord complications in non-gonorrheal epididymal infections which, though not uncommonly seen, are, judging from the literature on the subject, not well understood. The card catalog of the Massachusetts General Hospital, and I do not doubt that the same is true of other hospitals, contains a group of cases, cataloged as miscellaneous, in which indefinite diagnoses of "inflammation of the cord," "oedema of the cord," etc., have been made, in addition to epididymitis, by the operating surgeon. Clinically the cases are similar to the one described. It is with the purpose of contributing to this class of cases, one in which the etiological factor is evident, that this case is reported.

The patient, a man of 34, came to the accident room and was admitted to the hospital with the diagnosis of torsion of the cord. Family history was negative for tuberculosis. The patient stated that he had had a slight cough for several years but no sputum. He had had gonorrhea 14 years ago, had had treatment by a good man for eight months and had been discharged by him at the end of that period. He has never had discharge from the urethra since that time and has had no trouble with his urine. Two weeks ago he began to have chills, fever, vomiting and malaise but kept at work for a week, then went to bed. About that time he was caught with a sudden sharp pain in left upper quadrant which was worse on inspiration. He called a doctor who treated him for pleurisy by strapping the chest. This procedure gave relief. Three nights ago he awoke with sharp pain and swelling in the left scrotum. He found on examination that his pajamas had been pulled tight across his scrotum by his position in bed and were making pressure on the cord. The swelling has increased constantly since this attack of pain. His temperature at entrance was 99 degrees.

Physical examination showed no evidence of tuberculosis or of urethral infection. The left scrotum was enlarged, red and exceedingly tender. There was no evidence of fluctuation. The epididymis was thickened, the vas swollen and the cord thickened. Prostatic examination was unsatisfactory on account of the patient's fear of pain but the prostate seemed negative. The vesicles were not reached.

The urine showed the slightest possible trace of albumin but the sediment showed no pus. There were a few motile, gram-negative bacilli, apparently colon bacilli, in a fresh catheter specimen of the urine which were reported as colon bacilli by the bacteriologist. The white count was 23,000, 97% of which were polymorphonuclear leucocytes. Gonococcus complement fixation test was negative. Wassermann test was negative.

The left scrotum was poulticed for three days without improvement, then operation was determined upon. Preoperative diagnosis: Non-gonorrheal epididymitis.

At operation considerable edema of the subcutaneous tissues was found. The epididymis was engorged, deep red, with numerous small yellow abscess areas. The veins of the cord were thrombosed and the interspaces edematous and yellowish. The thrombosed veins were removed and multiple puncture of the epididymis done. Cover glass preparations from the pus in the epididymal abscesses showed no bacteria. Cultures from the same, no growth.

The pathological examination showed thrombosis of the veins of the cord with marked round cell infiltration of the tissue of the cord between the veins (Fig. 1). Sections of the cord stained for bacteria showed numerous short, gram-negative bacilli, probably *B. Coli*, in large masses in the thrombosed vessels but more numerous in the lymph spaces of the cord (Fig. 2).

The patient was discharged the eighth day. The left side of the scrotum was indurated but not tender and the temperature was normal. The patient was seen three weeks later and at that time showed no evidence of the operation save the scar.

FIG. 1.

Section of cord magnified 80x, showing thrombosis of a vessel and infiltration with round cells and a few polymorphonuclear leucocytes. There are bacilli to be found in the thrombus. Photo by L. S. Brown.

FIG. 2.

Portion of a lymph sinus magnified 1500x, showing large numbers of bacilli growing in the tissue. The bacilli have been treated by alcohol and formalin to make them retain the Gram-stain (Smith's procedure) for photographic purposes. Photo by L. S. Brown.

Book Reviews.

The Clinical Anatomy of the Gastro-Intestinal Tract. By T. WINGATE TODD, M.B., Ch.B., F.R.C.S., England. Manchester: Longmans, Green and Company. 1915.

This volume, which is the fifteenth in the series of medical publications of the University of Manchester, embodies a course of lectures on the alimentary canal as given by the author while professor of anatomy at Western Reserve University. The field is further limited by the omission of the mouth, pharynx, tongue and salivary glands, and aims chiefly at the presentation of a comparatively limited amount of new material incorporated with the classic facts of anatomy. It is not intended as a general textbook, but as an outline of recent work which has not yet found its way into the general manuals. Especial emphasis is laid on the clinical aspects of the subject. The old nomenclature is employed throughout, rather than the B.N.A. The book is illustrated by thirty-two admirable text figures. It concludes with an index and alphabetic bibliography of 355 references to authors quoted. It is a valuable contribution to research and knowledge in an important field of the modern higher anatomy.

Reports of Societies.

CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA.

THE SIXTH ANNUAL SESSION OF THE CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA WAS HELD IN BOSTON DURING THE WEEK BEGINNING OCT. 25, 1915.

An extensive and varied clinical program was successfully carried out during the mornings and afternoons at the various hospitals of the city. The general meetings of the Congress were held during the evenings in the ball-room of the Copley-Plaza Hotel under the presidency of Dr. John B. Murphy of Chicago and Dr. Charles H. Mayo of Rochester, Minn. The following is an abstract report of the proceedings at these meetings.

MEETING OF MONDAY, OCTOBER 25.

DR. JOHN B. MURPHY: *Ladies and Gentlemen.* As retiring president of this organization I have the pleasure of presiding this evening for a few moments. I will call upon Dr. Lund to deliver the address of welcome.

ADDRESS OF WELCOME.

By FRED B. LUND, M.D., BOSTON.

Chairman of Committee of Arrangements.

Mr. President, Ladies and Gentlemen: Boston has been defined, I do not know on how good authority, as not a city but a state of mind. Certainly a part of Boston has been in a state of mind ever since the Clinical Congress expressed the intention of meeting in Boston.

We can not show you any militant suffragettes or Zeppelins, but I believe you can see here as many feet of human colon removed as you did in London. We do hope you will like the place well enough so as not to want to get home on scheduled time.

Boston is proud of its medical as well as its historical interest. We have here some very fine hospitals. Some of our hospitals, which are closely connected with our medical schools, are the Massachusetts, City, Children's, Infants', Peter Bent Brigham, and Huntington.

We are glad to have the Harvard Medical School open for your inspection, yet we realize as well as you do that it is not the buildings but the men who make the hospitals and schools worth while.

It is an honor to our city that this Congress should care to meet here. We trust you will pass our imperfections by, and hope that where you see something good you will say that it is entirely due to the way the surgeons have worked together, and where there is something wrong you will say that it is because the surgeons could not avoid it.

As you know, Boston is tremendously interested in the war, and wonders when the end is coming. Perhaps it will be soon, perhaps not. It is a question whether there is any good to come from this war. When we think of the unspeakable sorrow and suffering, we feel there is not, but if there is any good it is the part taken by the medical profession. The war has sounded the death knell of anti-vivisection. We feel proud of the medical work and military

surgery done by Americans in this war. Dr. Strong of our Harvard Medical School has perhaps performed the most distinguished service during the war.

An opportunity will be given you to visit the battleships in our harbor, of which there are four. We hope you will look them over. I want again to thank you for coming to Boston. We will do our best to make your visit profitable and pleasant.

DR. MURPHY: Dr. William L. Rodman, who was to have been presented as president of the American Medical Association, was unavoidably detained through an accident. It was his intention to present a definite proposition. Dr. Albert J. Ochsner of Chicago may be called upon to present that proposition.

DR. ALBERT J. OCHSNER: Dr. Rodman has given the subject of a national board of examiners for the United States a great amount of thought. He received his inspiration upon this subject from the enthusiasm which this body has shown during the past five years of its meetings.

In order to take the position we are entitled to in the coming years we should do something to overcome the unfortunate arrangement which now exists with regard to medical education and medical licensing. There is no doubt that each state has a right to examine the medical profession. The manner in which this committee has worked out the examinations which shall be held by this board will be more thorough, and more complete and will be freer from any faults than any now held by various states. It will be left to any state to say whether or not any one who has passed this board shall practice in the state, but according to the plans which have been worked out, the examining board will be composed of such men as will be recognized from all parts of these states. They will be chosen from the medical schools, hospitals, libraries, and all the faculties of the medical department of the army and navy. They will not be controlled by any state. The requirements of preliminaries will be according to this department of the American Medical Association, at least. Each applicant must have a high school education, a college education, four years in a medical school, and must have served at least one year in a hospital as interne. That will not mean that it will be possible for any man to enter through a portal that is inefficient. This body has worked during these past years for the advancement of medical education and surgery.

I would, therefore, move the following resolution:

Resolved: That the Clinical Congress of Surgeons will support a national board of examiners according to the plan presented at San Francisco.

Seconded by Dr. MacRae.

Dr. Murphy then presented the motion for a vote and it was unanimously carried.

DR. MURPHY: Dr. Rupert Blue, president-elect of the American Medical Association, has been detained on account of business and cannot be with us tonight.

PRESIDENTIAL ADDRESS.

By JOHN B. MURPHY, M.D., CHICAGO.

On behalf of the executive committee I bid you welcome to the city of Boston. Boston is called the

seat of learning of the western hemisphere. I congratulate you on having the opportunity to avail yourselves of the many advantages of education and inspiration which the city and its people will place at your disposition.

As retiring president permit me to thank you all for the honor and privilege of presiding over this body. In describing the work of this organization it seems to me fitting to use the Scripture quotation from the book of Matthew, "By their fruits ye shall know them." Let us refer to the origin of this organization; and then I am sure we shall better appreciate its size, popularity, and personal interest. There was but one man who took up the task of its foundation and by his indefatigable zeal and courage, founded on the knowledge that he was working unselfishly and confidence that its members would appreciate it, he succeeded in establishing the Clinical Congress of Surgeons of North America. He first inspired a few, the few inspired a large number. I refer to its founder, Dr. Franklin H. Martin, the present secretary.

The popularity and enthusiasm of the men have created a great interest. As a matter of fact, only one-third of those who applied for tickets at this meeting could be accepted.

It has become an international enterprise. It invaded the British Isles. Through its clinics it creates an international fellowship. It brings the United States and Canada and all of North America in closer relation. It is to be hoped that the purely internal medical department will soon take a similar organization. The Congress had a right to speak and act for the surgeons of this continent. It appointed the foundation committee which founded the American College of Surgeons.

By asking the surgeon to keep reports, it causes him to compare these with works of others and, therefore, should increase his capacity. By improving the individuals it elevates the mass.

The membership and standing of this body command the respect and confidence of the world.

The Congress has appointed a hospital efficiency committee for the purpose of bringing together the members and superintendents of the hospitals for elevating the moral code of hospital work.

It also appointed a committee for the national control of cancer. The coming year it will take up this field of work in an organized and systematized manner. The medical profession can not advance materially in its practices beyond the lay information. The time has come when there is nothing known to the medical profession which can not be submitted to the lay press. No one has greater respect for the medical profession than those who are exactly informed on its scientific attainments.

We shall never have medicine freed from its impostors and counterfeiters until the laity is properly educated. The enormous service that can be rendered is shown through the coöperation of the public in the prevention and care of such diseases as smallpox, scarlet fever, diphtheria.

This organization has above all endeavored to democratize surgical teaching and surgical education. Each man is entitled to better opportunity. No organization can accomplish its best purpose without a mutual responsibility of the organization to the individual and of the individual to the organization. Kipling's "The Law of the Jungle" illustrates this very well.

... "The strength of the pack is the wolf,
And the strength of the wolf is the pack."

Dr. Charles H. Mayo, of Rochester, Minn., was then inaugurated president of the Congress in succession to Dr. Murphy.

INAUGURAL ADDRESS.

By CHARLES H. MAYO, M.D., ROCHESTER, MINN.

Ladies and Members of the Clinical Congress of Surgeons of North America:

I wish to thank you all for the great honor you have conferred upon me in making me your president as successor to Dr. Murphy, the greatest living teacher of surgical principles.

My subject is: "Errors of Development Along Anatomic Lines. The Causes of Such Errors and Their Surgical Consequences."

Errors of development are always of interest because of serious or fatal import connected therewith. Many anomalies are seen, but only those occurring in the human family can be overcome.

In searching for a cleavage line in the process of development it is interesting to compare animals of similar type, for the missing link is not so far removed from animal to man. All progress has been identified in the embryo. Occasionally changes have occurred in conditions pertaining to the vertebrates alone. Only the higher type of being has an opportunity for anomalies.

(The remainder of Dr. Mayo's address was a discussion of embryological errors of development and the importance of their bearing on surgical conditions in human beings. The address was illustrated with lantern slides showing comparison between different types of animals in the process of development.)

MEETING OF TUESDAY, OCTOBER 26.

THE DENTAL PATH, ITS IMPORTANCE AS AN AVENUE OF INFECTION.

By THOMAS B. HARTZELL, M.D., MINNEAPOLIS.

My plan in reading this paper is to emphasize the importance of the dental pathway as an avenue of entrance for general infection. I have brought material to you for your observation to confirm the point which I wish to bring out.

It is indeed true that the mouth, by reason of its size, is the host of an almost typical bacterial growth. One of the most important members of this flora is the streptococcus. I am well aware that I have no new material on the action of this organism. We all know that different parts of the body yield streptococcus to culture. Rosen offers definite and positive proof of the dental path of infection. The mucous membrane is a susceptible tissue to infection, and tooth structure is also, after eruption of the teeth, imperfect and capable of admitting infection. The lack of protection is well illustrated. When once an organism is in progress in the tissues it is liable to be carried into the blood.

There is a circulatory mechanism surrounding the tooth by which a mass of bacteria that penetrates the mucous crevice is easily taken into the

blood stream. If they do not gain access as just described, they may produce irritating toxins which are absorbed from the gum crevices. A further development, opening a route of destruction into the line of the crevice, causes ulceration.

In the study of serious dental abscess during the past year the staff at Minneapolis has attempted a definite and scientific investigation. This research has been carried on in laboratories of the school of medicine and has been assisted during the past year by the dental research department of the graduate school. In the laboratory procedure it has been our endeavor to prove or disprove the clinical infection. We have found that even bacterial culture obtained from abscesses may show individuals suffering secondary infection. From our first series of cases we are able to demonstrate lesions of heart muscle, and even secure the following photographs.

(The speaker then showed a series of photographs illustrating the histopathologic processes of local and general infections along the dental path.)

The subject of dental infection is so full of error as to command little respect. The remarkable vitality of dental pulp is shown in the fact that in about 50% of cases where a tooth is devitalized, the pulp may retain its vitality. Dental granuloma never takes place where pulp continues devitalized. It has been found that in toxemia resulting from a dental granuloma there is never great pyorrheal discharge.

CINEMATOGRAPHIC FILM SHOWING MOVEMENT OF BACTERIA AND AMEBÆ.

By WESTON A. PRICE, M.D., CLEVELAND.

I am very grateful for the last paper for, with few exceptions, it is the only case I know of in which a medical man coöperates with the clinical and dental profession. This is an unfortunate thing to have to say, but as a matter of fact all the papers and all the arguments I remember have been from medical bacteriologists and pathologists.

I regret exceedingly that it is not possible for me to present my discussion with motion pictures. We should also study the organisms of the mouth which we believe to be very largely responsible for the number of cases of pyorrhea. If I may discuss their neglect, I shall start by stating that there are probably good arguments for the amebic origin of pyorrhea. It has been found that probably 90% of peoples' mouths at certain times of the year, and probably during the most of May, June, and July, contain amebæ. Probably every person in the room, with an exception of maybe 1%, has that organism in his or her mouth. That is a very strong argument for emetin, administered in such dosage as to change the clinical symptoms. The dental pathologist who has been studying from 20 to 30 years over these lesions of the mouth and has seen certain stages of development, and has seen local improvement in their conditions, comes to recognize certain fundamental principles.

We have in this country an organization of men and women who do nothing else but treat that disease. At the last meeting they had an opportunity to compare experiences, and not one person a member of this society could report that in his experience in which he had tried faithfully and earnestly, except in one case, had been cured pyorrhea. What has happened? In many cases in my practice, in the practice of all these men, with these clinical

symptoms, certain changes have come into conditions in almost every person of whom intensive study has been made. It is sufficient to reduce the bacteria, and great improvement of clinical symptoms results.

Let me say that there are more patients in June and July in Cleveland without pyorrhea, with this organism in their mouths, than there were patients with it in their mouths in January and February. If I had time to go into detail of cases where we have had slides taken during November, December, January, February and March, of a type of pyorrhea, we should find that the organism was not present at any time when examined; at least we could not demonstrate its presence. During the weeks of February the conditions were slightly improved, during March and April organisms were found in greater abundance. There are now on record a rare number of such cases where this organism was present after April. It is a very definite bacteric picture, and if we had the motion pictures we should see in a certain type of men almost entire absence after use of emetine.

DISCUSSION.

By M. L. RHEIN, M.D., NEW YORK.

Infection we find seldom under pressure in and around the ends of the roots of the teeth. Statistics show that while the death rate in infancy and in early middle life has been steadily decreasing year by year, on the other hand from maturity to old age, until last year, the death rate from diseases of the heart, blood-vessels and kidneys has practical doubled in the United States in the past thirty years. Forty years ago the dentists in the United States did very little tampering with the pulp of a tooth. It was a rule to practice extraction as soon as there was pulp involved. Dentists felt that the acme of professional service was reached when, after the pulp had been removed, the tooth remained in comfort. Bacteriology twenty years ago had not revealed to us the presence of streptococcus in the ends of the roots of the teeth and that they could be present without causing the slightest irritation. A strong circumstantial point of clinical evidence to substantiate the fact of the increase in mortality due to faulty dentistry is found in the fact that during this period there has been at this advanced age a slight decrease in mortality. This appears to be due to the comparatively small amount of bridge work and the extensive extraction of teeth practiced.

ACIDOSIS IN ITS RELATION TO SURGERY.

By GEORGE W. CRILE, M.D., CLEVELAND, OHIO.

Plants and animals in their genesis may be biologically regarded as fundamentally the same. Animals, however, are detached from the earth and are contained within a water-proof covering so that acids can not be washed out. Moreover within animals may be enzymes by means of which harmful acid transformations are limited. The force of animation may also result from transformation of energy within the body. Elimination and energy transformation are associated with chemical acid reactions, some of which have even been made useful to organic functions. Thus we find that the respiratory center has been evolved to be controlled by the acid of the blood. Excess of blood-acid

causes acidosis. When it is necessary to increase the rapidity with which acid is produced one would expect to find that the mechanism which governs the circulation be speeded. One would also expect to find increased activity when acid is being produced. Surgically acidosis behaves as an intoxication with excess acid products which cannot be eliminated.

PROFESSOR LAWRENCE J. HENDERSON, Boston, read a technical paper on the chemical nature of acidosis, and DR. JAMES S. STONE, Boston, discussed the subject in the light of his surgical experience with children at the Children's Hospital, Boston.

MEETING OF WEDNESDAY, OCTOBER 27.

DR. MAYO: I have to announce that the annual meeting of this Association occurs at 12 o'clock tomorrow. The nominating committee is Dr. Simpson of Pittsburgh, Dr. Shering of California and Dr. Dodd of New York.

In the past we have become accustomed to hearing of the cure of so-called incurable lesions by taking out portions of the intestine. Tonight we are going to hear from some very conservative men about the real truth of the matter.

INTESTINAL STASIS AND ITS ACCOMPANYING SO-CALLED TOXEMIA.

By A. J. OCHSNER, M.D., CHICAGO.

The time allotted to me will be sufficient only to speak of the clinical, the practical part of the subject. There is not sufficient time for me to expose my ignorance on the toxemias. My colleagues who are versed in the scientific aspect of such things will dispose of that portion of the program.

So long as there have been authors in medicine the fact that the accumulation of excrement in undue quantity in the colon is harmful to the human being, and is the cause of disease, has been emphasized. Almost every author has a definite way of disposing of this difficulty. Institutions that are noted for restoring health, the watering places that have great renown, have attained their renown because of the laxative effect of the water found in their springs. The practitioners of medicine in all parts of the country have very commonly secured their high position because they have appreciated this fundamental principle. Proprietary medicines which have stood the test of time have all been based on the fact that they contained this property. Every language and dialect of every language has persisted in stating this fundamental fact. And so we might go on from point to point, bringing out prose and poetry to indicate that the colon must be kept empty in order to secure health to its owner. Just a few years ago mineral oil was introduced, and millions and millions of pounds of this have been sold to the laity and to the profession. Surgeons who have been successful have all insisted upon care of the colon after their operations; and so gradually during the last few years it has been made apparent that intestinal stasis is a terrible thing, and a thing which perhaps can be cured by surgical operation. This could be accepted only so long as it remained in the form of a fad. Just so soon as the element of faddism disappeared it has to come down to a

reasonable basis. The writings of Lane and explanations of Mixter and the hundreds of papers that have appeared all have the same tendency. They all show in the first place that intestinal stasis is harmful. These papers have discussed most thoroughly the study of the conditions with the x-ray. All of these have received an enormous amount of attention, but time will not permit us to go through them. The surgical treatment has been viewed from every imaginative and imaginary angle.

There are many opportunities for error in the study of patients. The clinician should be perfectly familiar with the variations in the normal subjects. The patient should be carefully studied before any action should be taken.

(The speaker now showed a series of x-ray plates.)

In our plates we have selected as nearly as possible the perfectly typical examples which show the general position of the colon. To the lay mind any one of these plates would serve as an argument which would induce them to submit to any operation. As a misunderstanding of these plates, many harmful operations have been done on the colon.

At any rate, we might say that in the wildest imaginations of the medical fakirs of the past ages no one would be able to conceive an idea which would so thoroughly impress the patient as could be done with this particular stuff, because in reading these x-ray plates you can read anything into them that you wish. If you know a great deal about them you can find it in these pictures.

In all the cases that I know of, less than 10% that came to our clinic for treatment of intestinal stasis really were operated upon. Four cases died. The other cases that died were cases that had suffered for so long a time that, with one or two exceptions, they really should not have been operated because they had no chance anyway. These cases represent less than 10% of those coming under our care during this year. A neurotic case showed marked improvement after operation.

In a large number the cause does not permit that the following of surgical treatment is necessary or will aid. The subject is of sufficient importance to deserve the careful attention of every surgeon. Much has been written of the bacteriology of these causes.

In regard to operative treatment, in a general way, if for any reason the obstruction cannot be removed, short-circuiting must be resorted to. It must be remembered that this operation should be considered very seriously as it involves great risk.

DISCUSSION.

DR. FRANK W. SMITHIES, Chicago: It is indeed a compliment to the internist and physiologist to be allowed to enter into the discussion this evening. Dr. Ochsner has given us all the proof necessary regarding intestinal stasis. Seeing that there is toxemia, it is up to us to discover what means are available for the improvement of the condition. We must discover the cause of such stasis by means of the x-ray.

It has been supposed that the excessive production of bacteria in the bowel permits of a greater absorption of bacteria than was thought possible. A great many of our cases indicate that this is true. Systematic feeding of the individual results in an improvement. It may be that persons with perfectly healthy bowels have

more bacteria in their blood than we have ever suspected.

In conclusion, it would seem that all instances of chronic stasis should be treated medically, but the medical man may require surgical aid.

After the removal of the causes,—bad teeth, adenoids, tonsils, etc., the internist is then ready to take care of the patient. When the patient comes with true surgical conditions, surgery is resorted to. Many times the removal of a gall-bladder relieves the stasis. The cure of pyloric obstruction will sometimes cure intestinal stasis, and all its symptoms. The chief part of the literature on the subject regards it as unmechanical. I cannot help but feel that we look only to operations for the result. In a case between a neurologist and a surgeon, the lawyer for the neurologist's side was asked, "Define a neurologist and a surgeon." "That's easy," said the lawyer. "A neurologist is a man who uses his brains; a surgeon is a man who uses his hands."

In going back to the question of fecal stasis, I cannot help but believe that each one of us must form a conception from his own and others' experiences. Now with my own experience I did more operating in the first half of the time than I did in the second. I am tending to advance backwards. The effect of our experience causes many of us to advance backwards.

I cannot help but feel that when we take a small intestine and try to make it do the work of the large, we are attempting the impossible. In some of these cases which have been operated on, after the recovery the constipation was increased. Now, as Dr. Ochsner says, how many of these cases may be relieved? I have taken only those cases of truly obstructive stasis. I have got 50% of good results. Is there any way out of this beside the present method?

Lane first maintains that forward anastomosis is the only way. Later he says forward and end-to-end anastomosis, then anastomosis of the ileum with the sigmoid direct.

DR. JOHN G. CLARK of Philadelphia: In what I have to say, I wish to emphasize what Dr. Ochsner said about discrimination in the case. It is difficult to determine what is primary and what is secondary. It is well to keep in mind the fundamental conditions of the action of the alimentary canal. It is a hollow organ. The function of this hollow organ is to be filled and then to empty itself.

These contractions, however, take place only under certain circumstances, so that as they fill they bring about a state of waves. This may be called tone. This state of tone causes contraction. What happens when this state of tone is present is, the muscle is stretched, the state of tone presses the point of contact, causing contraction. Thus the state of the organ must be filling up if the organ, by its content, causes a stasis.

Now the condition of tone in the alimentary canal is dependent upon the innervation of the whole alimentary canal. The vagus nerves share in the general conditions of the body. A depleted general condition is found in a flabby, weak person. The same thing is true of the alimentary canal. There may also be an abolition of tone and an inability of the alimentary canal to produce tone. This may be caused by worries brought about by emotional conditions.

Now we are in a position to understand how the general state of the organism may affect the digestive tract. If the patient is subject to worry or anxiety, that again will do away with the conditions which are fundamental for activity. Operations done in these circumstances are apt to leave individuals very much worse after operation than at the beginning.

I would like to urge or suggest a warning against kinks; they are not necessarily the cause of trouble. Kinks are found without stasis. I ask that you use your judgment in these cases, make a physiologic test, and be sure that mechanical conditions not only exist but are doing harm.

PLASTIC BONE SURGERY.

By FRED H. ALBEE, M.D., NEW YORK CITY.

(Illustrated by lantern slides.)

I will use the lantern entirely in demonstration, and first I would like to call your attention to the motor outfit which we use. Five years ago we began operations for inlay grafts and with the most crude instruments. We found there was no adequate apparatus to do the work with. From that time on we have been developing our instruments to do this work. I believe that in this line of plastic bone work, electrical power has a great influence. The surgeon is provided with a motor outfit, able to do the work much quicker and better. We can do almost anything that a carpenter can. Bone graft is placed on most impossible parts. It is remarkable how grafts will adapt themselves to their environment. The graft which is put in a part of the body will take on an unlimited amount of strength. I have used every joint which the carpenter uses.

(Dr. Albee showed the various kinds of grafts which can be made, the various kinds of joints, the splicing of the bones, (the use of the fish-tail joining seemed quite useful in many cases). He showed the instruments which he used, and the improvement in the methods which he now uses over those he had used before.)

MEETING OF THURSDAY, OCTOBER 28.

SYMPOSIUM ON MILITARY SURGERY.

Paper by GEORGE W. CRILE, M.D., CLEVELAND.

Read by DR. F. W. MARTIN.

We do not, any of us, regret any more than I, that I am to read Dr. Crile's paper, but it is absolutely necessary that it should be given in this place.

A group of weaklings pulling in the same direction yield a better result than a group of giants pulling in opposite directions. Our country has a vast supply of untrained men and raw material. Since the war began our manufacturers have had to learn how to make the things which we need and have before imported.

I suggested that it might be better to form a unit and that proposition was cabled to the American Ambulance hospital. The result was that this plan worked out so completely in France at the base that it was considered a competent plan.

If we are considering making such an organiza-

tion of the American reserve corps we must unite. Each man must be ready for the mobilization of the reserve force if it be required.

In general it would seem that the civil surgeon of the reserve corps should undertake no administrative duty. The civil surgeon should be exclusively devoted to the care of the patients. Those who come back from the front wounded need the devoted care of the surgeon and the surgeon must be prepared to render this service. I would, therefore, suggest that the first unit of the staff prepare for work in a well-organized hospital and that such a direction be distributed through all the good hospitals. The following personnel is suggested: A hospital of 500 beds; one chief surgeon, in charge; 5 associate surgeons with each in charge of one hundred beds; one orthopedic surgeon, and associate; one pathologist and assistant; one neurologist; one oculist; two dentists; and fifty nurses.

The apparatus should be owned by the government and set aside for each unit. The preparation and construction of these hospitals should be in charge of the regular army.

The following resolutions are suggested:

Resolved: That the Clinical Congress of Surgeons at its sixth annual meeting in Boston, October 29th, 1915, does hereby heartily commend our government in its efforts toward preparedness for war and it desires to express the purpose of its individual members to cooperate in any way possible with the medical departments of the Army and the Navy and the United States Public Health Service. Be it further

Resolved: That a copy of these resolutions be sent to the Surgeon-General of the Army, the Surgeon-General of the Navy and the Surgeon-General of the Public Health Service.

DR. MURPHY: You have all heard the resolution,—a serious one. It should be the pride of every man and of every country of the world to be prepared to do his and its full duty when the time comes. Two years ago at this date if anyone suggested such a resolution, he would have been considered a fit subject for the insane asylum. We must, therefore, as a medical organization, make known our desire to assume the full duty placed upon us. The medical profession has always been found ready to render such service when it has been called upon. I, therefore, take great pleasure in seconding that motion.

Paper by EDWARD H. NICHOLS, M.D., BOSTON.

I have been asked to speak on the organization of hospitals in England. The basis of administration of the English hospital is interesting. The hospital consists of 520 beds, twenty of which are kept for officers. The administration in these hospitals turned out to be almost identical with that of the Boston City Hospital.

The commanding officer is the colonel; under him come the major, captain, sergeant and orderly. The captain corresponds to the resident surgeon in the civil hospital. The sergeants and orderlies are nearly all men who before war received a complete training and are experienced male nurses. As to nursing, it is interesting to see the number of nurses required in these hospitals. The administration was carried on with great swiftness.

SYMPOSIUM ON CANCER.

By CHARLES H. MAYO, M. D., ROCHESTER.

The general subject of cancer is most important and the question for us, as surgeons and medical men, is have we done our whole duty to the public and if not, what more could we have done.

In the United States from seventy to seventy-five thousand people have cancers, so that our aim can not be too great in order to advance the question. Probably two hundred thousand people in the world are suffering with cancers. England had more women than men before the war. Five and one-tenth per cent. died of cancer between the ages of thirty-five and seventy. More people have cancers in the East than in the West. The young people went West leaving the old people in the East; thus those of cancerous age were all left behind. Now those who went West are becoming of cancerous age, therefore, cancer is increasing in the West also.

If we find a germ of cancer it will be an acid growing germ. The mouth is normally alkaline; as we advance down to the stomach, the great acid machine of the body, we find one-third of all the cancers that affect the human race. Cancers appear in acidulous regions. One of the rarest things you will find is cancer of the duodenum. You will not find it in the common duct and not in the lower portion of the duodenum. In the small intestine there is alkaline secretion. We come down to the colon, and the acid processes of fermentation there give rise to a large portion of cancers of the colon.

DR. CLARK.—I purpose to speak on the relative merits of the operation for cancer of the uterus. It is my firm belief that the organ in which cancer has developed should be removed. It is true that in cancer of the cervix the anatomical relation to the bladder and ureters tends to limit efforts toward its treatment. Heat has long been known to possess elective affinities for cancer. We became interested in this method about two years ago. Its value is so definite in advanced cases that serious consideration must be given its possibilities and its various uses in different stages of the disease. I believe that the cancerous uterus should be removed primarily or secondarily. For cancer of the body of the uterus vaginal hysterectomy is the cause of poor surgical risk. In the so-called inoperable cases we aim to stop bleeding and discharge, and occasionally convert what is apparently an inoperable condition into an operable condition. I do not believe that the cautery should be used from a curative standpoint. It should be combined with other measures and be looked upon more in the light of an adjunct. I became interested in the use of heat with a view of cooperating with other methods and primarily for the purpose of controlling the unpleasant complications. When you tie the internal iliacs, it is a splendid procedure.

DR. TAYLOR, New York.—I personally believe that there is a distinct value in the use of radium and cautery in cancer of the uterus. I believe that the surgical removal of cancer of the uterus is never destined to be abandoned. The selection of route of operation is important. There are the vagina and the abdominal. The abdomen is the preferred route. There are cases where this route is impossible. I prefer the abdominal route in all cases except where there is an excess of fat. I know that in my own work simple hysterectomy is the best

In the favorable case, the simple theoretical operation by the abdominal route may be used. There is more risk in the radical operation. I believe that the primary risk is not sufficient to outweigh the advantages of the more extended operation. I believe that the mortality in the future will be less if more care is taken in the surgery. Injuries to the ureters are accidental. While they can not be laid to carelessness they must be avoided. There is no doubt that injuries to the bladder are frequent. The separation of the bladder is more extensive in the radical than in the simple operation. In the radical operation the bladder is separated farther down on the vagina. Catheterization for a period of three weeks until the patient is up is not uncommon. Hemorrhages are serious complications and responsible for a number of deaths. The risk of infection is a definite one. Three per cent. of the deaths are due to some form of infection.

DR. J. F. PERCY, Galesburg, Ill.—A mass of cancer is destroyed when the temperature is raised to 112 degrees Fahrenheit and retained for ten minutes. In all forms of malignant cases we see where it is possible to use heat as the destructive agent. The use of heat is at all times valuable and of benefit in a large number of cases of the utterly hopeless type. In the hopeless type of cases the result is sometimes surprisingly good. By means of heat the patients lose their pain and have less dependence on morphine. My experience so far is that in large mass cancers the x-ray is a dangerous treatment. Heat destroys the neoplastic tissue. If I could destroy the growing mass completely, the patient could recover. This, unfortunately, heat will not infallibly do, and is, therefore, not curative. In my better judgment and better technique I am convinced, however, that by it a degree of palliation will be obtained that is worth while.

(The subject of the treatment of cancer of the uterus was discussed fully, by Dr. Percy and others, in the Cancer Number of the JOURNAL, July 13, 1915).

DISCUSSION.

DR. EDWARD REYNOLDS, BOSTON.

I have been given the difficult task of following the carefully prepared papers with a criticism of them. I have been unable to prepare. These papers bring before us a very interesting question in the treatment of cancer of the uterus by heat and by other radical methods. The subject of treatment of cancer by moderate heat is not a new one. I well remember that almost at the outset of my surgical career it was my privilege to come into surgical contact with the pioneer of the heat treatment, Dr. Burns of Brooklyn. The claims of those who have used the treatment have in the most part been difficult to believe and the profession has been skeptical. On the other hand, we must remember that they have not been downed. I am one of those who believe that the laboratory has not yet given us any strong evidence in the bacteriology of the disease. I do not believe that the use of moderate heat is the only or nearly the best means of preventing recurrence in the recently exposed tissues around the growth which is being removed. I am one of those who disbelieve in the use of the galvano-cautery or cautery in any form. I am one of those who prefer to use the cold steel knife, until they have taught us the

superior advantage of other methods; and I am willing to be taught.

ANNUAL MEETING.

At the annual meeting of the Congress held at noon on Thursday, October 28, Dr. Edward Reynolds, Boston, reported for the committee on cancer, speaking also as president of the American Society for the Control of Cancer. Dr. Ernest A. Codman, Boston, presented an extensive report on hospital efficiency and end-results, advancing in detail the method and plan for standardization which he proposes for adoption by hospitals throughout the United States. Dr. J. A. Hornsby, Chicago, discussed this subject. Dr. John W. Long of Greensboro, N. C., reported on first aid to the injured, referring to the recent conference on this subject in Washington, which was discussed editorially in the issue of the JOURNAL for October 21. He presented a resolution similar to the one adopted at this conference, which was unanimously passed. It was voted that the next session of the Congress shall be held at Philadelphia, and the following officers were elected for the ensuing year: President, Fred B. Lund, Boston; first vice president, Jasper Halpenny, Winnipeg, Manitoba; second vice president, S. M. D. Clark, New Orleans; general secretary, Franklin H. Martin, Chicago; treasurer, Allen B. Kanavel, Chicago; general manager, A. D. Ballou, Chicago.

AMERICAN COLLEGE OF SURGEONS.

The fourth convocation of the American College of Surgeons was held on Friday evening, October 29, at Symphony Hall in Boston. After an introductory address by Dr. John Miller Turpin Finney, president of the College, the candidates were presented by Dr. Franklin H. Martin, the general-secretary, and the fellowships and honorary fellowships were conferred by the president. The recipients of honorary fellowships were Dr. David W. Cheever, of Boston; Dr. Wilfred T. Grenfell, of Labrador; Dr. Stephen Smith, of New York; and Dr. Lewis McL. Tiffany, of Baltimore.

The fellowship address was then delivered by Rev. Edmund J. James, president of the University of Illinois, who discussed the relations of medicine and surgery with each other and with other of the forms of human occupation and service. He commented also on the intrinsic and extrinsic difficulties which have hitherto hampered the progress of medicine even more than that of other and cognate sciences. Following the exercises, an informal reception was offered to the Fellows and guests by the officers and regents of the College. The officers of the College, elected for the ensuing year are: J. M. T. Finney, Baltimore, president; W. W. Chipman, Montreal, and Rudolph Matas, New Orleans, vice-presidents; Albert J. Ochsner, Chicago, treasurer; Franklin H. Martin, Chicago, secretary; and John G. Bowman, Chicago, director.

THE BOSTON Medical and Surgical Journal

An independently owned Journal of Medicine and Surgery, published weekly, under the direction of the Editors and an Advisory Committee, by the BOSTON MEDICAL AND SURGICAL JOURNAL SOCIETY, INC.

THURSDAY, NOVEMBER 4, 1915

EDITORS.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States. \$6.56 per year for all foreign countries belonging to the Postal Union.

The editor will be in the editorial office daily, except Wednesday and Sunday, from one to two-thirty p. m.

Papers for publication, and all other communications for the Editorial Department, should be addressed to the Editor, 126 Massachusetts Ave., Boston. Notices and other material for the editorial pages must be received not later than noon on the Saturday preceding the date of publication. Orders for reprints must be returned in writing to the printer with the galley proof of papers. The Journal will furnish the first one hundred reprints for half the cost price.

All letters containing business communications, or referring to the publication, subscription, or advertising department of the Journal, should be addressed to

ERNEST GREGORY, *Manager.*

126 Massachusetts Ave., Corner Boylston St., Boston, Massachusetts.

CLINICAL CONGRESS OF SURGEONS OF NORTH AMERICA.

AFTER months of careful preparation the clinics and general meetings of the sixth annual session of the Clinical Congress of Surgeons of North America was successfully carried out in Boston last week. Between 1500 and 2000 members of the Congress were registered for the various exercises, and opportunity was afforded for all to observe the special or general work in which each was particularly interested. The plan of the meetings of this Congress, as outlined in his presidential address by Dr. Murphy, has now established its value in the emphasis which it lays on the clinical aspect of surgical and medical congresses. The Clinical Congress of Surgeons of North America has been a pioneer organization in this respect and the effect of its influence has been felt in smaller societies throughout the country.

Naturally the clinical exercises of the Congress do not readily lend themselves to journalistic report. The papers presented at the evening sessions, however, represent the summary of the experience of leaders in the profession and are of corresponding value in coordinating the material and ideas presented in the clinic. The full text of these papers and addresses are to be published in *Surgery, Gynecology and Obstetrics*, with the complete transactions of the Congress. The JOURNAL takes pleasure, however, in calling attention to its abstract report of these evening meetings which appears in another part of this issue.

The election of Dr. Lund as president of the Congress to succeed Dr. Mayo next year is a matter of pleasant gratification not only to his immediate friends but to the many members of the profession throughout the country with whom he is acquainted. In their behalf and in that of the JOURNAL we are glad to extend cordial congratulations to Dr. Lund upon this well-merited and honorable recognition.

Viewed in retrospect, the coming and the course of the Clinical Congress in Boston has proved of great value to the local surgical profession, not only as a stimulus to individual endeavor, but as an example of the importance of coordination between the different members and branches of the profession for the securing of the maximum of good judgment and technical efficiency from the point of view of the surgeon, combined with the optimum of beneficial end results from the point of view of the patient. It is our hope that the Congress may have proved, in some small degree, as helpful to our guests as it has to the profession of Boston.

DEMENTIA PRECOX AND CRIME.

THE factors of an etiological nature which are found to be operative in the genesis of crime and delinquency are indeed multiple. No dogmatic statements can be made concerning the all-importance of this or that provocative agent responsible for the outcropping of criminalism or delinquency of any sort. Those who are interested in the criminal and delinquent in general, particularly the juvenile offender, in whom, it must not be forgotten, the beginnings and evolution of these anti-social states are most

clearly and genetically seen, would do well to read, in fact to study, the recent excellent and comprehensive work entitled "The Individual Delinquent" by Dr. William Healy, Director of the Juvenile Psychopathic Institute in connection with the Juvenile Court of Cook County, Ill.

A recent paper by Dr. William J. Hickson, Director of the Psychopathic Laboratory of the Boys' Court of Chicago, will prove of interest since it is decidedly *à propos* of the general problem here mentioned, and because it directs our attention to a special causative factor in the production of criminal conduct. Hickson (*Illinois Medical Journal*, October, 1915) asserts that in all our courts, criminal and civil, one will constantly find a large percentage of cases of dementia precox which go unrecognized, although dementia precox, in a mild form, is really responsible for the condition present. In the Boys' Court of Chicago, for example, he states that the percentage of cases suffering from dementia precox in a group of 929 delinquents was no less than 15.6. The dementia precox occurred alone or was grafted on feeble-mindedness, in a certain number of cases being complicated with alcoholism, hysteriform seizures, simulation, and other conditions. He declares that most of the crimes of violence, rape and the like were committed by individuals afflicted with dementia precox, either pure or grafted on feeble-mindedness. Although paresis, manic-depressive insanity, epilepsy and the like were responsible for a certain number of the crimes, still their total number was practically negligible when compared with the frequency of dementia precox. As a consequence, Hickson goes so far as to say that, providing it be agreed not to call feeble-mindedness a psychosis, dementia precox might almost be regarded as the criminal psychosis *par excellence*. It must not be forgotten that, at the present time, and with the usual method of examination employed, dementia precox is frequently concealed and mistaken under many other diagnoses. In any case the importance of dementia precox should be recognized as a perhaps fruitful source of origin of many conflicts with the law. It should be searched for and unearthed just as we do in the case of suspected feeble-mindedness.

A further fact to be held in mind is that feeble-mindedness frequently has grafted upon it a dementia precox reaction. The author quoted above says that on an average of from

15 to 25% of the population of many institutions which harbor the feeble-minded are nothing other than cases of dementia precox, pure or grafted on feeble-mindedness. These cases are not recognized as such by those in charge, and efforts should be made to recognize them and transfer them to proper hospitals for the insane.

Dr. Hickson also mentions the fact that his laboratory has devised a system or method of psychological examination of such a nature that these tests are, in the matter of reliability and applicability, for dementia precox what the Binet-Simon tests are for feeble-mindedness. In the forthcoming report of the Psychopathic Laboratory a description of these tests will be given.

Although dementia precox may not be as frequent a causative agent of delinquency as one would conclude from the above statements, and although there may be much doubt and much difference of opinion in the diagnosis of borderline, early or latent cases of dementia precox, still the fact that dementia precox, pure or grafted on feeble-mindedness, is a not infrequent and perhaps even a common cause of criminalism, although appreciated by many at present, is forced home to us more strongly and more clearly by the remarks and conclusions here enumerated.

MIGRATION OF TUBERCULOUS PERSONS.

THE chief result of the investigation of interstate migration of tuberculous persons shown by a series of articles recently published in the *United States Public Health Reports*, written by service officials, entitled "Interstate Migration of Tuberculous Persons," is that local care is a better cure than climate without care. These reports cover investigations in principal health sections of the South and West.

This comment does not apply to the well-to-do, as they can travel with all comforts, can have constant competent medical supervision, have no financial worries, can devote their entire attention to getting well and are welcomed at nearly all health resorts. In fact, this class is the main source of income to some communities.

While tuberculosis spares no class of people, it is by large majority a disease of the working class, and it is to those that depend on their daily earnings for a livelihood for themselves and

family that the problem is different. In fact it becomes complicated, for with no intention to discredit the value of climate, it is unfortunate that money plays a very important part in the hope of recovery. Experience has taught that the disease usually picks its victim in the first half of life, in his most productive years, and yet before he has had time to make provision for such emergency. Vital statistics show the greatest percentage of deaths between the ages of twenty and thirty.

A common belief has been, and unfortunately still exists, that when one has tuberculosis all he has to do is to go to some well known health resort and the climate will do the rest. Many fail to realize that not only must the prevailing temperatures fit the individual but that climate, to give best results, must be free to the patient, to be out in it as nearly continuously as possible, day and night.

Rest, which is one of the first principles, can hardly be carried out in any way if the patient has but little funds and must seek employment. The question of employment must be considered, as these resorts are over-run with people seeking work. Most kinds of work naturally are not an aid and most employers do not care to hire consumptives if they can avoid it, therefore most of those seeking work find only disappointment.

If fever is slight most of these people are bound to try to save by neglecting medical supervision, thus tending to allow their condition to progress insidiously. For the same reason they go without comforts and proper food that they might have had in their homes. Naturally they sooner or later worry about their finances and often become homesick on account of separation from relatives and friends, with the result that suffering is increased or death steps in to claim the victim.

Not only must financial worry and homesickness be weighed in the balance, but it must be assured that the patient's physical condition is such that he can stand the travel with no ill effects. This last also applies to the question of sea voyage as well as railroad travel, for while ocean air may be very pure it is often too stimulating for a weakened and diseased lung. Far better may be the results by teaching intelligent attention to hygiene than to expect climate alone to be a magic wand.

Dr. Thompson Frazer of Ashville, N. C., has shown in the reports of his experience that, owing to the chronic character of the disease, improve-

ment is bound to be slow, and a case in the early stages must expect on the average to stay about a year. To do this a minimum cost of maintenance of \$700 outside of extras, carfare, etc., must be considered.

If home conditions are not satisfactory and a resort is advised, the patient and relatives should be given full knowledge of the obligations which must be met. Many arrive at resorts all but bankrupt and expect in a few weeks to join the ranks of wage earners.

If the importance of rest, good food and care are compared with the benefit derived from climate alone and its associated cost, much suffering may be avoided.

MEDICAL NOTES.

HARVARD MEDICAL SCHOOL OF CHINA.—The second annual report of the work of the Hospital Department of the Harvard Medical School of China shows an increase of patients treated of 100 over last year. About 30% of the total number were Europeans. Of the medical cases among Europeans, 82% were discharged well or relieved and 90.1% of the surgical cases. Of the Chinese medical cases 64.7 were discharged well or relieved, and 77.2 of the surgical cases. The table of diseases shows a preponderance among the Chinese of tuberculosis, that disease representing 13.5 of the total. There were 9% of traumatic cases, 6% of venereal disease 4.15% of beriberi, and 4% of malignant disease. There were five cases of opium habit and one of leprosy.

SOCIAL HYGIENE CONFERENCE.—The annual session of the Central States Conference on problems of social hygiene was held in Chicago on October 26. The principal address was delivered by Dr. Victor C. Vaughan, dean of the medical college of the University of Michigan on "The Duration of Human Life." He commented particularly on the notable increase of life expectation and of average longevity during the past twenty-five years.

CONTAMINATION OF SWIMMING POOLS.—THE JOURNAL has commented from time to time on the question of disinfection of public swimming pools. In this connection recent experiments by Dr. Wallace A. Mannheimer of Columbia University are of interest. Six pools were examined, ranging from 25,000 gallons capacity to ten times that amount, and varying from three users a day in a club to the Columbia tank with the student body bathing in it. In general it concludes that a large tank is always better than a small one.

"One of the tanks of 25,000 gallons filled with unfiltered Croton water was never in satisfactory condition even when calcium hypochlorite was used, while the pool of the club house was always in good condition, although no chemicals were used."

He goes on to state that "the factor not to be ignored in the condition of the sanitation of a bathing pool is the character of its patrons. The superior practice of hygiene by the college students makes their bathing place clean compared with a public establishment comparable in size, where with refillings every second day the bacterial count was high. All conditions considered, Dr. Mannheimer finds that filtration to clear the water of mechanical impurities and improve its appearance and chlorination to kill the bacteria, make an excellent combination. It is important to use the hypochlorite in the proper proportions. No comparison is here made with alum or other chemicals."

NEW YORK CITY'S HEALTH LAST WEEK.—During the week ending Oct. 23 there were in New York City 1296 deaths, with a rate of 11.64 as compared with 1216 deaths and a rate of 11.36 for the corresponding week of 1914. Health Department officials pointed out that while there were 80 more deaths reported during the past week than during the corresponding week of last year, 49 of these are to be accounted for by the increase in population. Considering the boroughs separately, Manhattan, The Bronx, and Queens showed a decrease in their death rate, Brooklyn and Richmond each an increase.

Measles, scarlet fever, diphtheria, croup and cerebrospinal meningitis showed noteworthy decreases in the number of deaths reported from these causes. Heart disease and chronic Bright's disease both showed an increase.

The mortality in the age group under one and under five years showed an increase. The rate for the first 43 weeks in 1915 is 13.23 as compared with 13.65 for the corresponding period of 1914.

ALVARENGA PRIZE OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.—The College of Physicians of Philadelphia announces that the next award of the Alvarenga Prize, being the income for one year of the bequest of the late Señor Alvarenga, and amounting to about \$250, will be made on July 14, 1916, provided that an essay deemed by the Committee of Award to be worthy of the prize shall have been offered.

Essays intended for competition may be upon any subject in medicine, but cannot have been published. They must be typewritten, and if written in a language other than English should be accompanied by an English translation, and must be received by the secretary of the college on or before May 1, 1916.

Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on

its outside the motto of the paper and within the name and address of the author.

It is a condition of competition that the successful essay or a copy of it shall remain in possession of the college; other essays will be returned upon application within three months after the award.

The Alvarenga Prize for 1915 has been awarded to Dr. J. E. Sweet, Philadelphia, for his essay entitled "The Surgery of the Pancreas."

MARKET SPECULATION IN QUININE.—It is reported that there is at the present time at least 200,000 ounces of quinine in stock in the United States, almost a year's supply. Nevertheless it is selling at \$2.50 an ounce, against 25 cents an ounce eighteen months ago. This extraordinary rise is due, it is said, to a speculative movement, and it is estimated that speculators have made \$500,000 in this country and \$1,500,000 abroad.

American manufacturers are receiving from abroad approximately 50% of their usual consignment of cinchona bark, solely from Java; so that, on the basis of bark shipments, the price, so the retailers complain, should not be much more than twice the usual price, or 50 to 75 cents an ounce.

Just after the European War broke out quinine went to 31 cents an ounce, and did not go above 40 cents an ounce until a few weeks ago, when this extraordinary speculation began. It was estimated that Oct. 1 the brokers had accumulated about 200,000 ounces."

PREVALENCE OF MALARIA, MENINGITIS, AND TYPHOID FEVER.—The weekly report of the United States Public Health Service for Oct. 15 states that during the month of August, 1915, there were in California 122 cases of malaria, 3 of cerebrospinal meningitis and 131 of typhoid fever. During the same period there were 145 cases of typhoid fever in Texas. During the week ended Sept. 25 there were six cases and two deaths of meningitis in New York City.

PRESENTATION TO A MEDICAL MAN.—At the twenty-fifth annual session of the New York and New England Association of Railroad Surgeons in New York City on Oct. 21, a silver loving cup was presented to Dr. George Chaffee of New York, founder and former president of the Association, by the other ex-presidents.

HUMIDIFICATION OF AIR.—With the advent of the winter season comes the problem, still unsolved, of the proper ventilation with sufficient humidification of air in artificially heated houses and public halls.

Some of the vagaries of present systems are presented in a recent pamphlet by Samuel H. Wheeler of Fairfield, Conn., who notes that sometimes as much power is required for the ventilation of a schoolhouse as for a machine shop, 150 horsepower for one high school being the figure given. The air in such an establishment is screened to exclude the dust, and washed, and when found too dry, is humidified and con-

ditioned, but after all it is not satisfactory. One experimenter has succeeded in evaporating into the atmosphere of a single steam-heated living room from six to eight quarts of water a day by a very simple capillary siphon. Six or eight quarts a day is very nearly what an ordinary furnace will dispose of in a day for an entire house, and the result is that with the coming of the shut-in season the walls and furniture begin to crack, and when the air finds it cannot get moisture from the inanimate objects in contact with it, it begins on the humans, and some widely distributed New England maladies are helped to efficiency by the lack of moisture in living rooms."

DEDICATION OF MAGEE HOSPITAL.—On Wednesday of last week, Oct. 27, the new buildings of the Elizabeth Steel Magee Hospital of Pittsburgh, Pa., were officially dedicated with appropriate ceremonies. The principal addresses were made by Dr. Charles Edward Ziegler, the medical director of the Hospital, and by Dr. Walter William Chipman, professor of obstetrics and gynecology at McGill University, Montreal. Following the addresses honorary degrees were conferred by the University of Pittsburgh in recognition of the occasion.

CONVICTION FOR DRUG MISBRANDING.—In the United States District Court recently the proprietors of Minard's Liniment pleaded nolo against a bill of information filed by the government alleging that the company misbranded its product in violation of the pure food and drug act. The government maintained that the liniment in question was incapable of performing all that was claimed for it on the label. The company was fined \$50 in lieu of costs.

EUROPEAN WAR NOTES.

RETURN OF AMERICAN PHYSICIANS.—Another party of American physicians returned to the United States on Oct. 20 aboard the steamer *Cretic*, which arrived in Boston on that day. The members of this party who had been serving in Serbia were Dr. Louise Taylor-Jones, who established a hospital for babies at Nish; Dr. Thomas W. Jackson of Washington, D.C., who succeeded Dr. Richard P. Strong as head of the American Sanitary Commission in Serbia; Dr. Joseph Thompson of Cleveland, Ohio; and Dr. George W. Mellon of Beaver, Pa., who will return to Belgrade after a three weeks' leave of absence in this country.

CHOLERA IN AUSTRIA-HUNGARY AND GERMANY.—During the week ended July 31 there were in Austria 2342 cases with 1286 deaths of Asiatic cholera, the majority being among the civil population. During the week ended Aug. 7 there were 2128 cases with 945 deaths. In Hungary during the week ended August 8 there were 565 cases of cholera with 312 deaths. During the

week ended Aug. 28 there were in Germany 267 cases of Asiatic cholera with 41 deaths, the majority being among prisoners of war. During the week ended Sept. 4 there was a group of 13 cases of cholera with one death at Danzig, and there was one case each at Breslau and Oppeln.

THIRD HARVARD SURGICAL UNIT.—The third Harvard Surgical Unit, whose organization was announced in the issue of the JOURNAL for Oct. 21, will sail from New York during November for service in a British base hospital somewhere in France. Dr. David Cheever of Boston was appointed as chief surgeon in charge of this unit and will have entire control of its activities from the time of its departure. The unit consists of thirty-six nurses and eight surgeons in addition to Dr. Cheever.

INCREASE IN COST OF DRUGS.—The price of many of the principal drugs continues steadily to increase with the progress of the European War and also as a result of the speculation based on disturbed market conditions. Report from New York on October 20 shows the comparative prices of some of the important drugs and chemicals on Oct. 19, 1914, Sept. 1, 1915, and Oct. 1, 1915, as follows:

	Oct. 19, 1914.	Sept. 1, 1915.	Oct. 1, 1915.
Bismuth subnitrate.....	\$2.55	\$2.70	\$2.80
*Bromides67	1.40	3.25
Caffein alkaloid.....	6.25	10.00	10.75
Carbolic acid38	1.50	1.70
Chloride of lime03	.02½	.05
Chlorhydrate58	.95	2.00
Norwegian cod liver oil.....	19.00	\$5.00	\$5.00
Glycerine C. P.24	.25	.60
Lycopodium70	.90	1.15
Manna82½	.80	1.05
Mustard oil, artificial.....	3.10	4.75	6.00
Opium	10.00	7.50	9.25
*Quinine, ounce31	.33	.40
Saccharine	4.50	8.00	8.50
Salol	1.05	6.50	7.25
Synthetic wintergreen oil....	1.00	1.65	2.85

* Nominal.

SHORTAGE OF PHYSICIANS IN RUSSIA.—In previous issues of the JOURNAL we have commented on the notable shortage of physicians in England, especially for the purposes of civil practice among the population at home, the majority of able-bodied physicians being required at the front. Apparently a similar condition prevail even more seriously in Russia, where a large part of the population is now entirely destitute of medical care. A recent issue of the *Lancet* makes the following statement on this subject:

"The Minister of the Interior, Prince N. I. Sherbatoff, has applied to the Minister of Education, Count P. M. Ignatieff, to consider measures for increasing the number of the medical men of the country. In his memorandum he observes that a large portion of the Russia people is now deprived of the possibility of medical assistance. In view of the insistent need

sity of taking advantage of all available medical aid, imperial permission was requested to put medical men of foreign universities, whether Russian subjects or subjects of allied or neutral countries, in Russian positions, as well as students attending the last courses of the medical faculties. But these extraordinary measures will not obviate the need for more permanent measures for the increase of the number of doctors. One of these specially indicated in the memorandum is the increase of the number of superior medical schools.

APPEAL FOR RED CROSS AID.—In a recent communication to the daily press Miss Mabel T. Boardman, national director of the American Red Cross, describes as follows the urgent needs of that organization for funds and supplies to relieve distress among the peoples of the belligerent European countries during the coming winter:

"The American Red Cross is receiving many urgent appeals from Europe for hospital supplies. From the American Relief Clearing House, Paris, H. O. Beatty, the director-general, writes:

"I think it will not be amiss to call to your attention the present situation in hospitals, in view of the coming winter campaign. The hospitals that have benefited so largely through the generosity of the American Red Cross are beginning to find themselves in a condition of real want for the common necessities. The demand for sheets, pillow cases and shirts is greater than ever. This is due to the fact of hard usage, and we should like to ask you to let us have as much of a supply as possible. The hospital organizations are much better than they were last winter, when in process of formation. We have a never-ending list of applications, also, for absorbent cotton, cotton batting and gauze. Of these we can never have enough. Chloroform and iodine, of course, are first necessities. May I ask that you let us have as much of these supplies as your resources will permit?"

"Another member of this executive committee, Charles Carroll, reports:

"As a member of the relief committee, I have lately been traveling through a part of Western France, and found several hospitals in shocking need of gauze, bandages, cotton and hospital garments. They were bravely making the best show they could under the circumstances, but they often never receive what is vitally necessary for their wounded. I was able, thanks to the American Red Cross, to materially assist the hospitals at Falaise and Argentan, where there was nothing in the way of supplies, and only the 36 cents allowed daily for each wounded man. This was absorbed by food and medicines, leaving nothing for bandages, gauze and cotton.

"I hope you may urge the shipment of as many hospital garments, as much absorbent cotton, bandages and other useful articles as it is

possible to send. The hospitals are crowded with the wounded from the recent battles, and everything that the American Red Cross can send over will be more than welcome to these poor sufferers. Our coffers and shelves are empty for the moment, and it is very painful to have to refuse and postpone relief which one knows may be the prevention of so much pain and suffering."

"Gen. von Pfuel, president of the German Red Cross, reports:

"Hospital garments and hospital bed linen would be very welcome. Also all surgical dressings, absorbent cotton, gauze and bandages of all sorts, and especially those three or four inches broad we can use to great advantage."

"As there has been a mistaken idea that the American Red Cross has ceased sending supplies to Europe, I write to say that we are shipping weekly large quantities of supplies to the various countries involved in the war, and, with the assistance of the public, will continue to do so. Circulars stating what articles are most needed will be supplied on application to the American Red Cross, Washington, D. C. All boxes of supplies should be sent to the American Red Cross, Washington, D. C. All boxes of supplies should be sent to the American Red Cross, Bush Terminal, Brooklyn, N. Y. Individuals wishing, may designate, if they so desire, to what country or to what particular institution their contributions are to be sent. Undesignated supplies are used by the Red Cross wherever the need seems to be the greatest."

Miss Louisa P. Loring, a Red Cross Emergency Secretary for Massachusetts, makes the following additional comment upon Miss Boardman's letter, with particular regard to the local work which is being done in that state:

"The Red Cross sewing circles in the different cities of Massachusetts are again taking up the winter work for the sick and wounded. The sewing room at 685 Boylston street is the chief authorized Red Cross sewing room in Boston. The Public Interests League is again generously giving rooms in this building for all who wish to make supplies for the European sick and wounded. The invitation is renewed to all to join in this work regardless of political opinion. Help is greatly needed, not only to make supplies, but for the materials to work with."

On Oct. 30 the totals of the principal New England relief funds for the European War reached the following amounts: Polish Fund, \$55,008.69; British Fund, \$35,179.36; French Fund, \$20,856.06; LaFayette Fund, \$10,878.99; Italian Fund, \$9,642.20; Armenian Fund, \$7,562.00; Surgical Dressings Fund, \$5,827.00.

BOSTON AND NEW ENGLAND.

PLYMOUTH DISTRICT MEDICAL SOCIETY.—On Oct. 21 the Plymouth District Medical Society held its annual fall outing at the State Farm, Bridgewater, Mass., as guests of Dr. E. B. Emer-

son, the medical director. There was an attendance of over fifty members, the largest out of the society has ever held. Dr. N. O. King of Brockton, Mass., presided.

Dr. Emerson read a paper on the farm, dating from 1852, and J. Arthur Taylor, master of the institution, spoke on the work. Medical Examiner Dr. A. E. Paine of Brockton, and Dr. Charles F. Whittington of Boston, president of the State Association, spoke.

INSTRUCTIVE DISTRICT NURSING ASSOCIATION.—The semi-annual report of the Instructive District Nursing Association shows a large increase in the volume of work accomplished over the preceding six months. Five hundred and four more patients were treated and a total of 2600 more calls were made. In all, more than 13,000 homes were visited.

FOOT AND MOUTH DISEASE IN MASSACHUSETTS.—After careful inspection of Worcester County, where the outbreak of foot and mouth disease occurred, Dr. Howard, Commissioner of Animal Industry, has withdrawn the quarantine from Brighton and public sale is allowed. The quarantine in Worcester County is released with the exception of the farm in Leicester where the disease occurred, and a radius of five miles from the farm. The Department of Agriculture at Washington has issued a pamphlet urging co-operation on the part of the individual for the common welfare and safety in the control of this disease. The great economic loss to the country should foot and mouth disease among cattle become general, as it is in Holland and Germany, is pointed out and the fear expressed that should swine become infected the entire industry might be wiped out.

TYPHOID AND SCARLET FEVER IN LEXINGTON AND ARLINGTON.—There have been reported in Lexington four cases of typhoid fever and twelve cases of scarlet fever, the latter all among children. The suspected source of infection is the milk supply but analysis of the milk has failed to reveal any traces of typhoid germs. In Arlington, near the Cambridge line, a total of sixteen cases of scarlet fever have developed. Most of the cases are mild and it has been thought not dren. The suspected source of infection is the children who contracted the disease have attended.

MASSACHUSETTS ASSOCIATION OF BOARDS OF HEALTH.—A quarterly meeting of the Massachusetts Association of Boards of Health was held in Boston on Thursday of last week, Oct. 28. After luncheon the following topics were discussed:

What are the present defects in the executive and financial status of boards of health of large towns of Massachusetts? Discussion opened by E. A. Ingham of Boston and W. E. Brown of York, Me.

What is meant by "Septic Sore Throat?" Discussion opened by Dr. Eugene R. Kelley of Boston.

Should boards of health furnish hospital treatment free to persons with certain contagious diseases? Discussion opened by Dr. F. P. Denny of Brookline.

Is there a need in Massachusetts for short educational courses for health officers? Discussion opened by Professor W. T. Sedgwick of Boston.

MASSACHUSETTS STATE CONFERENCE OF CHARITIES.—The twelfth annual session of the Massachusetts State Conference of Charities was held at Pittsfield, Mass., on Friday, Oct. 22. The general program of exercises at this meeting was published in the issue of the JOURNAL for Oct. 21. At the close of the session the following officers were elected for the ensuing year: President, Edward T. Hartman of Boston; vice-presidents, William F. Shannon of Northampton and Mrs. Ada E. Sheffield of Cambridge; secretary, George R. Bedinger; and treasurer, James A. McMurray, both of Boston.

MOVING PICTURES ON PUBLIC HEALTH.—It is announced by Dr. Allen J. McLaughlin, Massachusetts Health Commissioner, that the State Department of Health will furnish to such cities and towns of the Commonwealth as may make application therefor a series of moving picture films illustrating various topics of public health, with a lecturer to interpret the films. A series of six or eight different subjects has been prepared, such as Tuberculosis, Child Welfare, Adult Diseases, School Hygiene, Farm Health, and Cancer. The following cities and towns have already made application for the use of these films: Arlington, Cambridge, Billerica, Greenwood, Groton, Medway, Melrose, Millbury, Milton, North Wilmington, Hubbardston, Quincy, Rockland, Wales, West Medford, West Newbury, Waltham, Whitman, and Winthrop.

PREVALENCE OF DISEASE IN MASSACHUSETTS.—The monthly bulletins of the Massachusetts State Department of Health for August and September, 1915, present the usual data of the prevalence of diseases in this Commonwealth in that period. During the first seven months of the year 1915 there were in this state 38 cases of poliomyelitis, but in August there were 25 new cases and in September 14, representing 23 separate localities and communities. Seven of the total number of cases have been in Boston.

During the month of August 591 new cases of tuberculosis were reported as compared with 44 new cases in August, 1914. In September, 1915 there were 565 new cases of pulmonary tuberculosis and 58 of other forms of the disease.

There were 521 cases of diphtheria in August and 597 in September, 1915. In August there were 475 cases of whooping cough and in September, 450. There were 233 cases of typhoid fever in August and in September 321.

RED CROSS FIRST AID CLASSES.—It is announced that the First Aid Classes of the Massachusetts Red Cross are to be resumed during the current month. Anyone desiring to join these classes should apply at the Red Cross Headquarters, 603 Boylston Street, Boston. Dr. Richard P. Strong is honorary chairman, and Dr. George C. Shattuck, chairman of the committee in charge of the courses. Other physicians on this committee are Dr. Walter Howe and Dr. A. M. Fraser.

MEDFORD VISITING NURSE ASSOCIATION.—The annual report of the Visiting Nurse Association of Medford, Mass., shows a highly commendable activity on the part of that organization. The Association has three departments, that of the visiting nursing, the anti-tuberculosis committee and the bureau of friendly help. The visiting nurse has already demonstrated her important place of usefulness in any community. The number of visits made by the nurses last year in this city was 2270.

"The Anti-Tuberculosis Committee handled 24 cases during the year, of which 18 were definitely tubercular. The committee is a member of the Massachusetts Anti-Tubercular Committee, which embraces practically all similar agencies throughout the state.

"The Bureau of Friendly Help was established four years ago, during which period the volume of its work has greatly increased. From 374 visits, 130 office calls and 32 new cases in its first year, it had in 1915, 1582 visits, 844 office calls and 71 new cases.

"A sub-committee in charge of supplies received and distributed last year 1585 articles, exclusive of special gifts at Christmas and Thanksgiving. Clothing, household supplies, food and medicines go through the hands of the association, which, as a distributing agency, has peculiar facilities for knowing where is the greatest need, and relieving that need with least confusion or duplication."

MEMORIAL HOSPITAL AT IPSWICH.—It is reported that Richard P. Crane of Chicago, a resident of the summer colony at Ipswich, Mass., has announced his intention to give to that town a general hospital. It will be erected as a memorial to Benjamin F. Cable, a friend of Mr. Crane who was recently killed in an automobile accident.

Obituary.

WILLIAM GEORGE KIMBALL, M.D.

DR. WILLIAM GEORGE KIMBALL died at his home in Huntington, Mass., October 20, 1915, aged 68 years. He was born in Topsham, Vt.,

Dec. 25, 1846, the son of Joseph P. Kimball and Melvina Greene. He was a lineal descendant of Richard Kimball, who came to America from England in 1634 and settled within the present limits of the city of Boston. His minority, with the exception of three years spent in Illinois, was passed in his native state. He was orphaned in childhood and lived on a farm.

By his own efforts he gained an education, graduating from the Bradford (Vt.) Academy and Dartmouth Medical School where he received his degree in 1875. After graduation he became resident physician at Rainsford Island, Boston, and later held a similar position in the Hospital for the Insane at Northampton. In 1877 he was appointed assistant resident port physician at Deer Island, Boston. In 1879 he joined the Massachusetts Medical Society and moved to Worthington, staying there until 1885 when he took a post-graduate course in New York. That same year he settled in Huntington and had lived there ever since.

Dr. Kimball was a member of the Huntington Masonic lodge and was a Republican in politics. He served as chairman of the school board for seven years and held various other town offices. From 1899 to 1909 he served as medical examiner for Hampshire County and resigned then because of the interference of the office with his professional duties. He represented his district in the Legislature in 1895 and 1896.

In 1878 he married Miss Laura Bartlett of Claremont, N. H. Dr. Kimball is survived by his widow, his son, William J. Kimball, and three grandchildren, all of Huntington.

WILLIAM NOYES, M.D.

DR. WILLIAM NOYES, for fifteen years superintendent of the Boston Insane Hospital, died October 20, 1915, at his home in Jamaica Plain.

He was born in Boston, November 6, 1857, and was educated at Harvard College, where he was graduated with the class of 1881, and at the Harvard Medical School, graduating in 1885. In September of that year he accepted a fellowship in psychology at Johns Hopkins University. After a brief service as resident physician of the Baltimore Lunatic Hospital, he became an assistant at the Bloomingdale Asylum in New York. Still later, in 1889, he was connected with the McLean Asylum, then in Somerville.

"With the exception of a nine months' absence spent in study at Vienna and in Berlin, he devoted the next three years to the organization of a laboratory at McLean Asylum for special research in psychiatry and neurology. For three years he was assistant physician at the Hospital for Dipsonmanics and Inebriates at Foxboro. In April, 1896, he was appointed medical superintendent of the men's department of the Boston Insane Hospital, and later was placed at the

head of the institution. This position he resigned in 1910, when he again began to practice medicine.

He was a Fellow of the Massachusetts Medical Society, a member of the American Neurological Association and of the Boston Society of Neurology and Psychiatry.

Dr. Noyes married Miss Lucia M. Clapp of Montague in 1894. He is survived by his widow and two sons, William Noyes, 3d, a freshman at Harvard, and George Clapp Noyes.

Miscellaneous.

EVANS MEMORIAL LECTURES.

The Massachusetts Homeopathic Hospital has announced for the current season the following course of free public health talks to be given in the Evans Memorial Building, under the auspices of the Department of Clinical Research and Preventive Medicine on Tuesday evenings at 8 o'clock:

Nov. 2—"State and Municipal Health Precautions," Selskar M. Gunn.

Nov. 9—"Some Laws of Reproduction," Dr. A. W. Weyssse.

Nov. 16—"How to Secure Better Medical Service for Less Money," Dr. Richard C. Cabot.

Nov. 23—"The Immigrant and Public Health" (illustrated), Dr. George W. Tupper.

Nov. 30—"Mouth Hygiene: Its Relation to General Health" (illustrated), Dr. Leroy S. Miner.

Dec. 7—"The Care of the Feet" (illustrated), Dr. Gilbert M. Mason.

Dec. 14—"The Care of the Hair" (illustrated), Dr. Wesley T. Lee.

Dec. 28—"The Choice of a Vocation," Dr. DeWitt G. Wilcox.

Jan. 4—"Rational Child-Bearing," Dr. George H. Earl.

Jan. 11—"The Conservation of the Worker" (illustrated), Dr. Francis D. Donoghue.

Jan. 18—"The Air We Breathe" (illustrated), Dr. Helmuth Ulrich.

Jan. 25—"As a Man Thinks," Dr. Frank C. Richardson.

Feb. 1—"Facts About Sea Food" (illustrated), Dr. David L. Belding.

Feb. 8—"Sub-Standard Children," Dr. Walter E. Fernald.

Feb. 15—"The Taking and Giving of 'Colds,'" Dr. George B. Rice.

Feb. 29—"Occupational Diseases," Dr. David L. Edsall.

Mar. 7—"The Man of Fifty," Dr. Elmer E. Southard.

Mar. 14—"Occupation for Invalids" (illustrated), Miss Susan E. Tracy.

Mar. 21—"Change of Life," Dr. Eliza B. Cahill.

Mar. 28—"The Brain," Dr. Solomon C. Fuller.

April 4—"How the State Provides for Its Mentally Sick" (illustrated), Dr. L. Vernon Briggs.

April 11—"How to Choose a Doctor," Dr. W. P. Bowers.

April 18—"Microbe Invaders and Our Defenders" (illustrated), Dr. W. H. Watters.

April 25—"Sleep and Dreams," Dr. Edward Wyllys Taylor.

May 2—"Summer Care of Babies" (illustrated), Dr. Karlton G. Percy.

May 9—"Demonstration in Public Health Nursing," under the direction of Miss M. H. P. Bridges.

SOCIETY NOTICES.

THE HARVEY SOCIETY.—The second lecture of the series will be given at the New York Academy of Medicine, 17 West 43d Street, on Saturday evening, November 6, 1915, at 8.30 P.M., by Prof. A. J. Carlson, University of Chicago.

Subject, "Recent Contributions to the Physiology of the Stomach."

NORFOLK SOUTH DISTRICT MEDICAL SOCIETY.—Stated meeting at United States Hotel, Boston, Thursday, November 4, 1915, at 11.30 A.M.

Dr. A. J. A. Hamilton, of Boston, will give a Lantern Demonstration of Gastric and Duodenal Ulcers for Dr. Charles Whelan, of Hingham.

F. H. MERRIAM, M.D., *Secretary*.
South Braintree, Mass.

NEW ENGLAND PEDIATRIC SOCIETY.—The joint meeting of the New England Pediatric Society, Pediatric Section of the New York Academy of Medicine and the Philadelphia Pediatric Society will be held in Philadelphia November 8, 1915.

The day will be spent in visiting the various hospitals, clinics and laboratories.

At 8.30 P.M. the following papers will be read:

"Lobar Pneumonia: the Co-Relation of Its Symptoms and Physical Signs with the Findings of the Roentgen Ray." Dr. Howard H. Mason, New York.

"Studies on Tuberculosis in Infancy." Dr. Charles Hunter Dunn, Boston.

"Experimental Studies and Clinical Values of the Guinea-Pig Test for the Virulence of the Diphtheria Bacilli." Drs. John A. Kolmer, Samuel S. Moody, Emily L. Moshage, Philadelphia.

NOTICE.

CENSORS' EXAMINATION.

The Censors of the Suffolk District Medical Society will meet to examine candidates for admission to the Massachusetts Medical Society at 8 The Fenway, on Thursday, November 11, 1915, at 2 P.M.

Candidates, who must be residents of the Suffolk District or non-residents of Massachusetts, should make personal application to the Secretary and present their medical diplomas at least three days before the examination, between the hours of 4 and 5 P.M.

DAVID CHEEVER, *Secretary*.

355 Marlborough St., Boston.

LEGISLATION FOR THE INSANE IN MASSACHUSETTS, WITH PARTICULAR REFERENCE TO THE VOLUNTARY ADMISSION AND TEMPORARY CARE LAWS.*

BY FRANKWOOD E. WILLIAMS, M.D., BOSTON.

Executive Secretary, Massachusetts Society for Mental Hygiene.

THE number of persons suffering from mental disease in Colonial times does not seem to have been sufficiently great to have made much of a problem. Neither the Colonial nor the Provincial laws make any reference to the class, with the exception of two provisions: one in the Body of Liberties (1641), providing that "Children, idiots, distracted persons and all that are strangers or new comers to our plantation shall have such allowance and dispensations in any cause, whether criminall or other, as religion and reason require,"¹ and the other in the Colonial Laws of 1641, providing that "Any conveyance or Alienation of land or other estate what so ever, made by any woman that is married, any children under age, idiot or distracted person, shall be good if it be passed and ratified by the consent of a General Court."²

The first Massachusetts law providing for the

care of insane persons was passed in 1797.[†] The method adopted in providing this care is of particular interest, as it speaks eloquently of the general conception of insanity held at the time. In 1788, a law had been passed entitled, "An act for suppressing rogues, vagabonds, common beggars and other idle, disorderly and lewd persons,"[‡] which provided commitment to the house of correction by two justices of the peace. When, in 1797, the general court wished to provide for the insane, it amended the act of 1788 by inserting in the list with "rogues, vagabonds, common beggars and other idle, disorderly and lewd persons," the words "lunatic persons."

At the opening of the nineteenth century, insanity, in the opinion of most people, was a moral rather than a physical disease. Devilcraft was largely given up, but the theological idea that had taken its place—that insanity is pure mental and moral perversion, and represents the outbreak of the animal and violent elements of the fallen human soul which have culpably been permitted to get the upper hand of the higher attributes—was hardly more favorable to the sufferers from mental disease. To be sure, leaders in Europe had been urging that insanity was a disease comparable to physical disease. Rush had read a paper (1786) before the American Philosophical Society, "On the Influence of Physical Causes upon the Moral Faculty," and some practitioners were leaning feebly towards this idea. One physician "after forty years' experience" wrote (1806) that he was "not sure" but was "inclined to think in-

sanity due to a morbid condition of the brain."⁷³ But the idea was not popular, and made little headway against the religious, moral and metaphysical notions of the time. Insanity was a disease of the mind, it was held, and the mind was the seat of the soul. The relation that the brain might have to all this was little regarded. That insanity was a moral disease found strong expression even as late as 1830. Coleridge, in his "Table Talks," probably expressed the opinion of most educated people of the time when he wrote:—

"Madness is not simply a bodily disease.

It is the sleep of the spirit with certain conditions of wakefulness; that is to say, lucid intervals. During this sleep or recession of the spirit, the lower or bestial states of life rise up into action and prominence. It is an awful thing to be eternally tempted by the perverse senses. The reason may resist—for a time; but too often, at length it yields for a moment and the man is mad forever."⁷⁴

Thomas Cooper, M.D., (1831) in the preface to his translation of Broussais' "On Irritation and Insanity," speaks with intense feeling of the enmity of the clergy and the ignorance of the medical profession on the subject of the somatic nature of insanity, and so great did he feel the opposition and ignorance to be that he incorporated in the book a tract on materialism and a paper, "An Outline on the Association of Ideas."⁷⁵

John Barlow, in 1843, writing "On Man's Power Over Himself to Prevent or Control Insanity," said, "... the being sane or otherwise, notwithstanding considerable disease of the brain, depends on the individual himself. He who has given a proper direction to the intellectual force and thus obtained an early command over the bodily organs by habituating it to the process of calm reasoning, remains sane amid all the vagaries of sense; while he who has been the slave, rather than the master of his animal nature, listens to its dictates without question, even when distorted by disease—and is mad. A fearful result of an uncultivated childhood!"⁷⁶

The trustees appointed to superintend the construction of the Worcester Lunatic Asylum make note of this popular feeling in their first report, stating that "the universal opinion has been that it (insanity) was an awful visitation from Heaven, and that no human agency could reverse the judgment by which it was inflicted."⁷⁷ They take a position against this view, but further in their report show how firmly entrenched the metaphysical conception must have been in that they were not wholly free of it themselves. In outlining their plans for the treatment of patients they provide, if necessary, an attendant to each patient, "whose duty it is to remain constantly at his side to occupy his (the patient's) attention with pleasant themes

... to soothe and pacify that portion of the mind which had been excited to frenzy and so to allow those faculties whose action remained undisturbed to gain the ascendancy."⁷⁸ Further, they are to provide for their patients beautiful scenery, so that "the restorative influences of nature may strike some chord in the heart as yet unbroken in the fatal struggle with worldly disappointments."⁷⁹

Amid such conceptions, the McLean Hospital was opened in 1818. Insanity being considered incurable, the hospital was planned to serve humanitarian purposes rather than medical. It is interesting to observe that no new legislation relative to the status of insane patients was considered necessary upon the opening of the hospital. The law of 1797 was still in force, and a new law had been passed in 1816 providing that any person acquitted of crime because of insanity might be committed to jail by any justice of the supreme judicial court until he recovered. But neither the law of 1797 nor the law of 1816 affected the McLean Hospital. Access to it was as free and upon the same basis as access to any hospital. The hospital was opened for the care of persons suffering from insanity whose friends or family desired them cared for, and it seemed quite logical and proper at that time that such persons should be received in the same manner as another member of the family might be admitted to the Massachusetts General Hospital.

During the late twenties, a new interest was aroused in the insane. Word came from the better hospitals of England and this country that the condition in its early stages was largely curable; that the insane neglected in cages and pens, cellars, outhouses, prisons and almshouses were hopeless, but much, if not all, of this could be prevented if insane individuals were given proper treatment sufficiently early. On the wave of enthusiasm created by this new idea, the Worcester Lunatic Hospital was ordered built, and was opened in 1833. All persons to be committed thereafter under the laws of 1797 and 1816 were ordered committed to the custody of the hospital at Worcester, and all confined in jails or houses of correction under order, decree, or sentence of any court, or any judicial officer by virtue of the above statute were ordered to be sent to the Worcester Hospital as soon as practicable.

Up to the time of the opening of the Worcester Hospital patients were committed by order of any two justices of the peace or by a justice of the supreme judicial court. With the opening of the Worcester Hospital, the power of committal was taken from the justice of the peace and bestowed as follows: "Judges of Probate in all counties except Suffolk—in Suffolk the Judges of the Municipal Court—in addition to the Justice of the Supreme Judicial Court and the Court of Common Pleas."⁸⁰ The law of

* Acts of 1832, Chap. XCv.

1833 further specifies that the judges shall commit those "so furiously mad as to render it manifestly dangerous to the peace and safety of the community that such lunatics should continue at large." It did not call upon the judge to decide, nor give him right to decide, whether the person before him were sane or insane, but whether he was "so furiously mad" as to be a danger to the community. The obvious intent of the law was not that the judges should control the admission of patients to the hospitals, but that they should be given power to commit those who might resist such admission and whose presence at large would be a danger. This law did not prevent the free access to the hospitals of those who desired such admission. Admission to the Worcester Hospital was as free and informal at this time as had been the admission to the McLean Hospital in the preceding fifteen years. That the law was so conceived and understood is borne out by the fact that the superintendent in his reports notes those who have been committed "by friends" without court action, and urges friends and relatives to bring their insane patients as early as possible.

Further evidence of this interpretation is the law passed in 1836, which provided that "the trustees may also, in their discretion, receive into the hospital for a less sum (than the actual expense) any poor persons suffering under recent insanity, whether supported or not by any town or city."[†]

Public care of insane persons was new in Massachusetts. There were no precedents to follow. It is not surprising, then, that a spirit of uncertainty as to the best method of procedure should be manifested in the changing of the laws from time to time during the early years of the hospital. In 1834, a provision was added to the effect that "Any person or persons making application (for commitment) must first give notice in writing to the selectmen, or either of them, in the town, or to the mayor of the city where such lunatic resides, of the intention so to apply" and that "satisfactory evidence that this has been done be presented to the judge."[‡] This provision was slightly changed in 1836.[§]

In 1837, trial by jury was provided for.^{||} This provision for a jury in cases of lunacy did not come from distrust of the hospitals or their officers, nor from any feeling that the determination of lunacy was a lay or legal rather than a medical matter. It must be held in mind that at this time access to the hospitals was free, and that the courts were called upon to decide merely whether a patient's madness made him a sufficient danger in the community to warrant his forcible detention. The suggestion for a jury trial came originally from Dr. Samuel Woodward, first superintendent of the Worcester Lunatic Hospital. In his fourth annual

report (1836) he had cited the fact that the courts have a right to commit any persons who are a danger to the community, had asserted his confidence in the courts, but had added, "the spirit of our institutions is adverse to the uncontrolled exercise, by any tribunal, of so great a power as this. It should guard with scrupulous jealousy against every possible encroachment upon the liberty of the citizen under whatever pretence; and we would respectfully propose such a modification of the statute as would in every case, recur to the individual or to his friends, if they should think proper to claim it, the right to have the facts in the matter of dangerous lunacy determined by a jury."[¶]

In 1839, a law was passed authorizing the City of Boston to build a hospital.* Power of commitment was lodged with the municipal court. In 1840, this power of committal in Boston was taken from the municipal court and given to the police court "saving to the person complained against the right to appeal from such order to the Municipal Court of the City of Boston."^{††}

By 1840, opinion in regard to the method of procedure seems to have been settled, and from that time until 1853, a period of thirteen years, no changes were made. In fact, no serious changes were made after the law of 1833 had been slightly amended in 1834. For a period of practically twenty years, the procedure outlined in these laws was followed, and the hospitals were permitted to perform their service without further legal obstruction.

The Worcester Hospital opened its doors under very favorable auspices. The plan for taking the insane from their former wretched surroundings, caring for them, and restoring them to health and usefulness was very popular. The hospital was hailed as the "state's greatest charity" and was a source of great pride to the commoner. But the hospital had been opened under a misapprehension, with hopes that could not be fulfilled, and the results of this, and the conscientious mistakes made by the early superintendents and trustees in encouraging these false hopes, are still to be noted today. The commissioners who had been appointed by the governor of the Commonwealth to supervise the erection of the hospital at Worcester,—Horace Mann, Bezaleel Taft, Jr., W. B. Calhoun,—said in their first report, "It is now most abundantly demonstrated that with appropriate medical and moral treatment insanity yields with more readiness than ordinary diseases." Further, that "fifty, sixty, and in some instances ninety per cent. recover in well regulated institutions." "As early as 1827," says Pliny Earle, "by a combination of fortuitous and favorable circumstances, Dr. Todd of the Hartford Retreat was able to report the recovery of 21 out of 23 recent cases of insanity received into that institution.

[†] Revised Statutes, Chap. 48, § 8.

^{||} Acts of 1837, Chap. 228, § 1.

* Acts of 1839, Chap. 131.

^{††} Acts of 1840, Chap. 79.

This remarkable result was reduced to a formula and the percentage (92.3) thus derived from less than one-quarter of a hundred cases was published and became more or less a criterion by which to measure the possibilities of all recent cases."¹⁰

As Earle points out, the decennium 1827-1837 was an age of big men—Woodward, Bell, Ayl, Butler, Brigham, Kirkbride, Stribling, Ray, McFarland. These were men of rare abilities, loftiness of purpose, and enthusiasm. Their very enthusiasm, however, carried them into a competition that proved in the long run harmful. "Before each of them stood the stimulating and provocative precedent of erroneous percentages, and around each of them was the competitive ability of his colleagues in the specialty. It is no cause for marvel that under these circumstances a public opinion was formed upon the curability of insanity too favorable to be sustained by the experience of the future. This opinion was enunciated by a few superintendents at an early date, but considered as an established idea in the minds of the people, it was the fruitage of the decennium in question more than of any other in the whole history of the past; and thenceforward it has very generally been claimed that of all cases of insanity of less duration than one year, from 75 to 90% are susceptible of cure. For more than forty years with respect to a few, and more than thirty years in respect to many, this has been the shibboleth of the superintendents of hospitals and of other writers upon the subject of mental alienation; and especially has it been depended upon as one of the crowning arguments in favor of the establishment of new hospitals and the enlargement of old ones, and of appeals to hesitating and reluctant legislatures for additional appropriations of money for the completion of unfinished ones, for which the purse of the Commonwealth has already been taxed beyond the bounds of reason and of patient endurance."¹¹

The first annual report of the Worcester Lunatic Hospital states that of 25 recent cases, 12 had been discharged cured. The second report gives the total per cent. cured as 55.75; old cases cured, 20.5; recent cases, 82.25. The third report gives 82.50% of recent cases cured. In 1840, Dr. Woodward prepared a table which showed that 88% of those who had been insane less than one year were cured, 57% of those insane from one to two years, 37% of those insane from two to five years, and 11% of those insane from five to ten years. This table was used by Waterson in his "Report on the Condition of the Insane in Massachusetts in 1843," as an argument urging provision for greater facilities at Worcester.¹² and eleven years later, in the report of the commission appointed to report on insanity and idiocy in Massachusetts,¹³ the statement is still made that if the disease be submitted to proper remedial measures, three-fourths or nine-tenths may be restored, and this

proportion of the patients made again self-supporting members of society. Other hospitals throughout the country were making the same favorable reports. In 1841, Pliny Earle, later superintendent of the Northampton State Hospital, compiled the following table from the reports of the various hospitals:¹⁴

Asylum.	Time.	Percentage of Cures in Recent Cases.
Dr. Burrows'		91.32
Vermont State	3 years	89
Vermont State	1840	88.20
Massachusetts State	1833-40	87.20
Massachusetts State	In 1840	91.25
Ohio State	1839-40	85.50
Bloomington	In 1839	83.87
Retreat, Conn.	6 years	75.95
Retreat, Conn.	4 years	91.60
Average,		87.10

There is no doubt that the superintendents in publishing such figures intended to be honest both with themselves and with the public. The error lay in the method of computation. The percentage of cures was based, not upon the number of patients admitted, but upon the number discharged, so that a hospital having received a hundred patients during the year, and having discharged 24, of whom 12 were cured, reported a percentage of 50 instead of a percentage of 12. A further mistake was made in counting the number of cases discharged instead of the number of patients. Six recoveries might represent but one person, admitted and discharged six different times during the year. In one hospital, one woman was reported recovered nine times in two years; in another, five persons 32 times; in a New York hospital, "for one woman, 46 recoveries were reported in the course of her life, and she died upon her 59th admission."¹⁵

Encouraged by the hope created by the figures given above, legislatures all over the country were quick to build hospitals, hospitals built were soon filled to overflowing, and additions or new hospitals were erected. During this period of confidence and expectation when the hospitals enjoyed the enthusiastic support of the community (1833-1858) the Worcester Lunatic Hospital was twice enlarged (1835, 1843); the Boston Lunatic Hospital (1836), the Taunton (1854), and Northampton Hospitals (1858) were built. So great were the demands made upon the hospitals that the superintendents soon became engrossed in the many detailed problems of hospital management. At the formation of the Association of Medical Superintendents of American Institutions for the Insane, in 1844, sixteen committees were appointed, only five of which pertained in any way to medical subjects, and one of these was on the "Moral Treatment of the Insane." The papers read at the meetings of the Association were largely upon subjects of hospital management, such as, "Proper Size of a Hospital," "Dietary," "Building," "Proper

Number of Patients to an Institution," "Relative Value of Different Kinds of Fuel for Heating Purposes." In the early meetings of the Association, little or no mention is made of legal matters, but later (1863-69), stung by adverse criticism, the Association found it necessary to devote a great deal of its time to the consideration of this subject. That the views of even these leaders of psychiatry were still tinged with metaphysical conceptions, even though they were urging the physical view, is evidenced in the causes of insanity assigned by them: "Indulgence in temper," "mortified pride," "agitation on the approach of matrimony," "metaphysical hair-splitting," "predisposition excited by novel reading," "the complete gratification of every wish of the heart." Another cause that is of interest today, although not a metaphysical one, is "changes from ordinary to vegetable and abstemious diet."¹⁶

The superintendents in the early days were autocrats. This is not surprising in view of the fact that at that time all physicians were more or less autocratic. Unlike the present day—when any person who has reached the high school age apparently has a right to opinions upon medical topics, and when there are almost as many views upon medical subjects as there are persons in the community—the physician was the only person in the community who was supposed to understand medical matters. When he took charge of a case he took command. He expected his judgment to be taken, and his directions to be obeyed. The superintendents were medical men, and medical men primarily, and they naturally felt that they alone should know what was best for their patients. They resented interference in the care of their public patients as they would have resented it in the management of private cases. This attitude was accepted by the public without question at first, but later came to be resented. One of the principal methods of treatment used at that time was the so-called "moral" treatment, an "entire change of surroundings, whereby all existing trains of associations are broken and the mind is introduced to new persons, new things and new scenes."¹⁷ In carrying out this plan of treatment, correspondence and visits of friends and relatives were frequently denied. The motives for such treatment were misunderstood, and further antagonism was aroused.

During the twenty years just discussed, the hospitals have had little or no opposition. It was becoming apparent, however, by the end of this period that the hopes held out in the beginning were not being fulfilled. It had been found that insanity was not so easily cured as had been supposed; that many of those who had been pronounced cured in the early beginnings had sooner or later become again insane; that aside from what had been accomplished from a humanitarian point of view, little had been accomplished of permanent value. The high hopes of 1833

were dashed by 1853, and the reaction that might have been expected, augmented by the ill-feeling that had developed as the result of the autocratic attitude of the superintendents, and the misunderstanding that had arisen from the isolation of the patients while being given "moral treatment," set in. Discontent and suspicion began to take the place of confidence and enthusiasm. This restlessness is noted in the legislation. Although there had been practically no change in the legislation for twenty years (1833-1853) in the ten years from 1853 to 1863, the method of procedure in insane cases is changed five different times.* The most noteworthy change was made in 1862, when the phrase in the early law, "so furiously mad as to render it manifestly dangerous to the peace and safety of the community that such lunatic should continue at large," was changed to read, "any insane person who in their opinion is a proper subject for treatment and custody." The law further provided that "in all cases the evidence and certificate of at least two reputable physicians shall be required to establish the fact of insanity."

This law was the first bolt, as it were, driven into the doors of the hospital, making more difficult their inward swing. From the opening of the McLean Hospital until the day this act was approved—a period of 44 years—admission to the hospitals had been without formality for those who desired admission or whose friends desired admission for them. The number thus admitted varied from year to year, depending upon the number of vacancies at the hospitals. The law required the hospital to admit all regularly committed to it as "dangerously mad," and the number of those commitments frequently left little room for voluntary, or, as they later came to be called, "bond" patients. Dr. Woodward drew attention to this repeatedly in his reports. In 1836, so many patients had been sent by the courts that only eight private patients could be admitted. He complained that chronic, incurable patients, at times idiotic and imbecile persons, not "dangerously mad" were being sent to the hospital, filling it up, crowding out the more hopeful early voluntary cases, and thus defeating an important purpose of the hospital. On one occasion he suggested that the trustees be given power to refuse admission to committed cases when the hospital was full, in order to obviate the necessity of discharging voluntary patients before they were fully recovered.¹⁸

And one is privileged to wonder if this abuse of the law and of the hospital was not in his mind when he urged that in certain cases the "furiously mad" and "dangerous" condition of a patient be determined by jury.

The effect of the law of 1862 was soon felt. Dr. Bemis, the superintendent, in his report for 1863,¹⁹ comments as follows:—

* Acts of 1853, Chap. 19; Acts of 1856, Chap. 108; G. S. (1860) Chap. 73, Sect. 8; Acts of 1860, Chap. 73, Sect. 10; Acts of 1862, Chap. 223, Sect. 8.

"The recent laws regarding the signing of certificates of lunacy by physicians have operated in an unfavorable manner upon the admission of a few patients into the hospital, and must prevent the early admission of patients afflicted with certain forms of mental disease. The necessity for two physicians to testify to some definite fact which is of itself sufficient to prove insanity, is easily fulfilled in cases of acute mania, when the mind of the patient is completely absorbed in his present feelings and impulses, and has neither power nor inclination to exercise caution. In other forms of insanity, however, equally destructive in the end to all the reasoning and controlling powers of the mind, proof is not so readily obtained; the evidence is cumulative, and the patient retains much of his capacity for concealing symptoms and eluding the inquiries of his physician, and often refuses altogether to see a medical man. In this manner the patient escapes the treatment calculated to remove his disease, until it has become incurable. Sometimes a well meant but mistaken friendship takes such a direction and exercises such an influence as to prevent the admission of the patient; or if it does not prevent admission, so disturbs the relation existing between patient and the hospital as to retard recovery and promote disorder and dissatisfaction. This difficulty is the source of great suffering to many families in this Commonwealth, who are obliged to bear the burden and anxiety consequent upon the care of some insane member, until the disease becomes continuous and incurable. Hospitals were undoubtedly created and endowed for the public good, and to answer a want felt by the community. Let the laws controlling admission to their wards be so humanely framed as to open their doors to any diseased member of society, and let the benefits, if any, be conferred alike upon every grade of mental suffering. Establish commissions for investigation, if necessary, guard them with the most zealous care; but while they are hospitals, make them also asylums, to which every sufferer may flee for comfort and help, or not longer enact laws which attach to the character and conduct of a residence in a hospital for the insane the stigma of prison life and discipline. Surround them with the most generous safeguards. Endow them with every facility for treatment and every comfort and convenience for their inmates. And by giving a generous impulse to public opinion, already favorable, assist in their elevation." The irritation that is detected in a part of this paragraph from Dr. Bemis's report is evidence of the pressure of adverse criticism that the hospitals were beginning to feel.

By 1863, the feeling had become sufficiently strong to force the passage of a resolution directing the governor and council to appoint a commission "to examine what changes, if any, are necessary in the laws regarding insane persons."⁶ The commissioners appointed,—Josiah

Quincy, Jr., Alfred Hitchcock, M.D., and Horatio R. Storer, M.D.,—made a report²⁰ wholly favorable to the hospitals, but the defense of the hospitals that the commissioners felt it necessary to make speaks plainly of the change in feeling that had taken place in twenty years. "Are patients wrongfully detained in insane asylums?" is the question the commission first finds it necessary to answer. "It has been thought," says their report, "that there is a possibility that two physicians may be found who, either in ignorance of the varying and deceptive symptoms of the particular disease, or through interested motives, may certify to insanity when ungoverned passions or jealously only render a removal from the family circle desirable, and that superintendents might be bribed to keep the person in confinement." The commissioners reported that they had found no such case, and that the character and interests of superintendents made such a contingency improbable. They found it necessary to say further: "It is the opinion that the care of the Massachusetts hospitals for the insane is, at the present moment, in honest hands. . . Too little allowance seems hitherto to have been made for the excessively delicate and responsible position here occupied by Trustees and Superintendents, who, if worthy of appointment to their posts, should also be thought worthy of confidence and trust."

The popular feeling that was beginning to gather at the time is still more clearly shown in the statement that "it has been suggested that so-called 'protectors' of the insane be appointed to have no connection with any hospital, either as officer or trustee, who should have authority at certain or at all times to visit these institutions and examine the patients in general, or particular patients, and decide the question of the propriety of their retention; and by special statute, that patients should from time to time be allowed to write letters to their friends and others." The commission replied that these "protectors" could be no more depended upon than the trustees and "cannot be supposed to be such judges of insanity as those who have made the disease a study and who have opportunity to observe the patients in question from day to day." The commission, among other things, recommended a commission in lunacy, license for private hospitals, requirement for the detention of any person alleged insane, the certificate of two responsible physicians and the abolition of commitment by judges save in criminal cases.

Following the report of this commission to the legislature, in 1864, a law was passed providing for the licensing of private hospitals.* Favorable to the hospitals as was the report of the commission, the public feeling was such that the legislature felt it necessary to pass a law providing that "On petition under oath to any Judge of the Supreme Judicial Court, setting forth that the petitioner believes that some person confined as insane in any hospital or other authorized

* Acts of 1864, Chap. 288, Sect. 8, 9.

† Acts of 1864, Chap. 288.

* Acts of 1863, Chap. 81.

place for the treatment or restraint of insane persons, is not insane, and is unjustly deprived of his liberty, the Judge may, in his discretion, appoint three commissioners to inquire into the alleged insanity of the person so confined."[†]

Continued and growing discontent with the hospitals is shown in the legislation of the next ten years (1864-1874). Changes in legal proceeding or antagonistic legislation directed at the hospitals or their officers was passed five different times in this period.[‡] A feeling that persons were detained in hospitals and driven mad by their associates, developed rapidly and found expression in a commission appointed in 1874 to report "what alteration of or addition to the laws are necessary to guard the rights of the insane; what improvement may be made in the rules of the asylums touching attendance, general treatment of patients, and freedom of correspondence, and add all suggestions as their investigations may prove to be necessary. . . to guard and aid, etc. . ."[†] The two commissioners, Nathan Allen and Wendell Phillips, made separate reports.²¹ Each found grave danger to personal liberty in the methods of commitment then in vogue. Allen notes "that there has grown up and existed for some time an antagonism of feeling and interest between hospitals, the superintendents and trustees as a body, and the general public." He quotes one trustee as saying, "It seems as if the public believed that every man connected in any way with a hospital for the insane had entered into a conspiracy to deprive the patients of all of their rights and to do violence to all the relations of life." The prejudice, he says, springs from an impression that the managers of hospitals are unwilling to discharge patients when they have recovered. As to the officers themselves, he says: "While they (superintendents, officers and trustees) have their rights, which should be respected and properly treated, they do not own the institutions, neither are the latter run for their emolument. While their opinions and counsels come largely into account and they have a controlling voice in managing the hospitals, there are other parties, inside and outside, who have rights therein, and whose opinions are entitled to consideration. The claim and interest of these latter parties are vastly greater and more important than those of the former."

Phillips reports that the present methods are wholly wrong and dangerous and liable to great abuse. He doubts if a physician should be applied to in any case. Samuel E. Sewall, whose letter to the commissioners is incorporated in their report, is even more emphatic in his denunciation of the system, stating that it is based upon the false principle "that personal liberty is of little consequence," and urges that the question of an individual's sanity should be left with the judges.

[†] Acts of 1864, Chap. 288; Acts of 1865, Chap. 268; Acts of 1867, Chap. 355; Acts of 1871, Chap. 321, Sect. 1; Acts of 1874, Chap. 363.

[‡] Acts of 1874, Chap. 363, Sect. 3.

The senate committee on public charitable institutions, to which the report was referred, reported²² that it did not think it expedient to recommend any legislation in accordance with the suggestion of the commission. It further stated that "many of the complaints brought to the notice of the commission were trivial, some more serious, but taken care of by Trustees, and that, considering the large number of persons dealt with, the complaints were comparatively few." The members asserted also their confidence in the superintendents and trustees.

This report marks the high water mark of ill-feeling and distrust. The tide turns. Until 1879, there was no new legislation affecting the status of patients, and in 1882 a period of constructive legislation began, which in the thirty-three years that have followed has made Massachusetts a leader in enlightened legislation dealing with the care and treatment of those suffering from mental disease.

During these years there have been other forces at work, and if ill-feeling and distrust reached its culmination in 1874, these new forces began to find expression about 1882. There were several tributaries to this stream. It may be said to have started with the abolition of the theory of demoniacal possession; to have been augmented by the work of Pinel in France, the Tukes and Connolly of England, who demonstrated that chains and cages and other forms of restraint were unnecessary in the treatment of the insane; to have been helped by the teaching that insanity is curable, although as we have seen, this hope was greatly exaggerated and led to a degree of harm; and finally the "general acceptance of the somatic and the rejection of the psychic theory of insanity by establishing psychology on the basis of physiology and pathology—a scientific movement anticipated by John Hunter, begun by Bichot and Esquirol, carried out by Griesenger and Virchow."²³ The researches into pathology, anatomy, physiology and psychology, and later those into bacteriology and psycho- and neuro-pathology, have brought the question of insanity from the cloudy mysticism of metaphysics into the light of scientific conceptions, and established it as a disease among other diseases, and its sufferers patients to be treated on the same general basis as other patients. This new point of view is reflected in the legislation and thought of the present day. As has been mentioned, it first found expression in 1882 with the passage of the law* restoring voluntary admission to the state hospitals, and has found expression since in the Emergency Act, the Observation Law, and finally in the Boston Police Law, the Seven-Day Temporary Care Law, and the establishment of a psychopathic hospital for the care of early cases of mental disease and for research into the causes of mental disease and the means of prevention.

Massachusetts has six laws providing for the

* Acts of 1881, Chap. 272, Sect. 7.

temporary care of insane persons: that for the apprehension of an alleged insane person. (Sec. 34, Chap. 504, Acts 1909), the Emergency Law (Sec. 42, Chap. 504, Acts 1909), the Observation Law (Sec. 43, Chap. 504, Acts 1909), the Boston Police Law (Chap. 307, Acts 1911), the Seven-Day Temporary Care Law (Chap. 395, Acts 1911), and the Voluntary Law (Sec. 42, Chap. 504, Acts 1909.) Of these six laws, four provide care without the necessity of court action. And it is in this that their great significance lies. This freer access to the hospitals seems like a new development. And for this generation it is a new development. As a matter of fact, however, it is but getting back to the fundamental conceptions of a hundred years ago. It has been pointed out how in the beginning access to the hospitals was free. Patients needing treatment could receive it without application to the courts. How for many years this continued, but how, through a growing prejudice and misunderstanding, due to the false hopes created in the minds of the people by superintendents who honestly entertained these hopes themselves; through the distrust which arose because friends did not sufficiently understand the object in isolating patients; through the fear that developed that individuals were being improperly confined, and that personal liberty was being violated, regulations pertaining to the admission of patients to the hospitals became more and more rigorous, until the time came when there was an almost insurmountable legal barrier about the hospitals. A medical matter became a legal matter. A judge who would hesitate to diagnose a case of heart disease exhibited no hesitancy in making a diagnosis of mental disease. And no matter what might be the opinion of some half dozen earnest and conscientious students of mental disease, the lay opinion of the judge decided the diagnosis. Happily this stage is being passed. It was well to have gone through it. The medical man, trained to note the physical and pathological aspects of the problems presented by his patients, and probably inclined to be a little careless of other considerations, has been taught that his patients do present other problems; that he is not a law unto himself, and that the personal liberties of his patients must be zealously guarded. The member of the bar, on the other hand, properly jealous of any violation of personal rights, has come to realize from the serious results that have followed upon unfortunate decisions, that the problem is after all a medical one, and one that only careful students of such conditions can hope properly to solve.

Considering the uncertainty in regard to the true nature of mental disease, the metaphysical and theological mysticism in which it was a generation ago enwrapped, it is not surprising that all this misunderstanding should have arisen. But as we have seen, the researches of the last twenty-five years have dispelled this mysticism:

have placed mental disease solidly in the ranks with other diseases; and have established the sufferers from such disease as patients, to be treated and cared for as patients. This conception is making it clear that an individual bereft of his reason has rights as an individual that must be protected, but that in protecting his rights as an individual we must not forget that he has rights as a patient, and that the hope of soon regaining his rights as an individual may largely depend upon the consideration that is given at a critical time his rights as a patient.

The Voluntary Admission Law provides that any person desiring admission to a hospital for the insane for the purpose of treatment may be admitted on his own application, providing he is sufficiently clear mentally to understand the nature of his act. The law further provides that no voluntary patient may be detained in a hospital longer than three days after that patient has given notice in writing that he desires to be discharged. Originally only those persons able to pay for the expense of their care and treatment could be admitted under this law, but in 1906 the act was amended so as to include all persons needing treatment. In an endeavor to see how generally this law has been used, Southard²⁴ has gathered statistics of admissions under it since 1895. From 1895 to 1899, 405 patients were admitted under this law to the state hospitals, including the McLean Hospital. From 1900 to 1904 there were 520. In other words, from 1895 to 1904 this act served in about a hundred cases a year. Beginning with 1906 there is a gradual increase, as shown in the following figures:—

Year.	Total.	Vol.	%
1906.....	2670	125	5
1907.....	3022	156	5
1908.....	3195	195	6
1909.....	3096	185	6
1910.....	3254	200	6
1911.....	3207	237	7
1912.....	3250	282	8
1913.....	4051	636	16

Since 1895, then, 5401 patients have been able to receive treatment in our state hospitals under this act without formal process of law. The law serves particularly those individuals who fear that they are becoming insane and wish advice and treatment. Many of these are psychoneurotic patients, who are not insane, but who much need proper and expert advice in order that they may successfully readjust themselves; some are patients in the early stages of mental disease and therefore greatly in need of care. Others who submit themselves under this law are early or mild dementia praecox cases, early depressions, and more frequently than would be supposed, early cases of general paresis. Eversole,²⁵ in a study of 389 voluntary admissions at the Psychopathic Hospital in 1913 found that 101 had been diagnosed "not insane," and 288 "insane." Of the 288 insane patients, 31 were cases of general paresis, and 66 cases of dementia praecox. None of the psychoneurotic patients, few of those suf-

fering from the earlier manifestations of mental disease, many of the early *præcox* cases, mild depressions, and cases of early general paresis would not be committable in the regular form, and would be unable to obtain treatment except for this law. And when it is considered that every patient suffering from the depressed form of manic-depressive insanity is potentially suicidal, and that every patient in the early stages of general paresis is capable of grave social and economic wrong, the value of such a law to the individual and the community becomes apparent.

The Boston police law, providing that the police of Boston shall bring to the Psychopathic Hospital all persons brought under arrest who appear to be suffering from mental disorder, need not be discussed at length as it applies only to the Boston District. It is of interest to note,²⁸ however, that of 1523 admissions to the Psychopathic Hospital last year, 426 were admitted under this law. The law is particularly significant in that it provides for these individuals as patients rather than as criminals. The mother who becomes suddenly insane and hurls her baby from a second story window, the man or woman who, suffering from delusions of persecution, endeavors to wreak vengeance on his imagined persecutor, the petty thief or shoplifter with grandiose delusions that she owns an interest in a large department store, the hallucinated individual who is found scouting about the Fenway looking for "the enemy," instead of being taken to jail to be associated with real malefactors until such time as they may be examined and regularly committed (in the summer time probably three or four days), are taken immediately to a hospital where they are understood and properly cared for as sick persons. Although this law is not applicable outside the city of Boston, the same ends could be gained in the outlying districts by a wider use of the seven-day law on the part of police officials and physicians.

The seven-day law is applicable in any part of the state. This law provides that "any physician, member of the board of health, or police officer in any city or town, an agent of the Institutions Registration Department of the City of Boston, or member of the district police, may request the superintendent or manager of any hospital for the insane to receive for a period of seven days and care for any person needing immediate care and treatment because of mental derangement."

This law serves both as an emergency law for use when courts are not in session, or when, for one reason or another, there would be considerable delay in commitment, and as a very useful observation law. The use as an observation law is probably the more general in those hospitals where it is most frequently used. We are getting past the point where we are willing to wait until a depressed patient attempts suicide, a patient suffering from delusions commits homicide, or a patient in an early stage of mental disease

ruins his family financially by foolish ventures, and are coming to see that both society and the individual are best served when these things are prevented. Sudden insanity is a comparatively rare thing. The beginning is usually insidious; for weeks or months before a frank attack the friends and family note that the patient is not "just himself," that his actions and conversation are somewhat peculiar or unusual. The patient himself is frequently puzzled, does not understand himself and wonders what may be the matter with him. In self-defense, however, he often asserts, if questioned, that there is nothing wrong with him. The family physician, if called, notes the peculiarities, has a feeling that the patient is "not just right," but does not feel that he can say that the patient is insane, and decides to wait for further developments. These developments come only too frequently in the form of some act that shocks not only the physician and family, but the community. Scarcely a day goes by that the newspapers do not carry one or more stories of suicide in fits of depression, or homicides by insane patients, or both. The people of Boston were recently shocked when they read in their morning papers that during the night a well-known and respected young man had murdered his wife and three children and had then committed suicide. The family physician had been observing the young man for several weeks, "had a feeling" there was something wrong with him, and had said to the wife that if he did not get better soon, he would send him to a hospital for observation. While the physician was waiting, the young man took his case into his own hands. Fortunately, accidents of this magnitude are not frequent, but the case is typical of its kind. And it is in such cases that the seven-day law can be used to advantage. In using the seven-day law it is not necessary to assert that the patient is insane; there is reason to believe that the patient is not right mentally, and in order to obtain a diagnosis and proper treatment and advice as early as possible he is sent to the hospital, where such advice and treatment may be received. The abuse of this law lies in physicians sending to the hospitals under its provisions, frankly insane cases about whose mental condition there is no doubt. Such cases should be regularly committed, as no advantage accrues to the patient through such period of observation, while the temporary care machinery of the hospital is liable to be clogged and made less efficient by any appreciable number of such cases.

Experience demonstrated that seven days was frequently not sufficient time in which to determine the patient's mental condition, and the time has therefore been increased to ten days by the present legislature.* This will be sufficient in the great majority of cases. Some cases, however, require weeks rather than days, and in such the voluntary law and the law providing

* Acts of 1915, Chap. 174.

TABLE I.—TEMPORARY CARE.²¹

Cared for without action by court.....			387	577	1016	1512
Per cent. never requiring commitment.....			51.91	49.02	48.65	54.64

* Replaced in 1911 by No. 7, the seven-day temporary care law (Chap. 395, Acts of 1911) which has in turn been replaced by Chap. 174, Acts of 1915, increasing the time limit from seven to ten days.

court commitment for a period of observation, usually 30 to 60 days, complements the temporary care law.

A study of the temporary and voluntary care statistics in the state reveals some interesting facts.

Table I shows the number of patients admitted to the Massachusetts hospitals for temporary care since 1909. The number has grown from 325 in 1909 to 3043 in 1914. The laws designated as 1, 2, and 3 require action by courts. Admission under 4, 5, 6 and 7 is informal and without court action.

The number of patients admitted under the latter group has grown from 187 in 1909 to 2767 in 1914. Since 1909, 7295 patients have been able to receive treatment in the hospitals without formal application to the courts.

In 1914, of the 2767 patients admitted without court action, 1128 were discharged without commitment, 34 died before commitment, 235 signed voluntary requests and 115 voluntary patients continued their stay in the voluntary status, no commitment being considered necessary. Thus 1512 persons were able to secure the benefits of treatment in the hospitals for the insane without the delays, the legal exactions and the semi-publicity that comes with a procedure before a judge. This number, 1512, represents 54.64% of the patients admitted informally. In 1913 the number was 1916, or 48.65%; in 1912, 577, or 49.02%; in 1911, 487, or 51.91%. Since 1911, 3492 patients have found it possible to be admitted to the hospitals, to receive treatment and to be discharged without formal procedure.

Tables II and III show the distribution of the cases discussed under Table I.

TABLE II.—TEMPORARY-CARE CASES, 1912.*²²

	Vol.	Emergency.	Temp. Care.	Total.
Boston	93	10	545	648
Westboro ...	58	3	44	105
Danvers	22	0	63	85
Taunton	7	0	50	57
Worcester ...	12	2	42	56
Northampton.	19	0	34	53
McLean	71	0	14	85

It is to be noted that the great preponderance of cases have been admitted to the Boston State Hospital, Psychopathic Department.

In 1912 (Table II) the Psychopathic Hospital received 648 temporary care cases. The other six hospitals of the state combined (including the McLean Hospital) received but 441. There was a difference of 543 cases between the number received at the Psychopathic Hospital and the number received at the Westboro State Hospital, second highest on the list.

TABLE III.—TEMPORARY CARE CASES, 1913.*²³

	Vol.	Emergency.	Temp. Care.	Total.
Boston	448	18	623	1094
Danvers	25	0	80	105
Westboro ...	56	0	42	98
Taunton	5	0	77	82
Northampton.	22	0	50	72
Worcester ...	6	2	50	58
McLean	74	1	15	90

The same disparity is noted in the figures for 1913 (Table III). While the number of temporary care cases at the Psychopathic Hospital increased from 648 to 1094, the increase in all the other hospitals combined was but 64. The second highest number for any one hospital (Danvers State Hospital) was the same as in 1912, 105 cases. There were 260 more voluntary cases admitted to the Psychopathic Hospital

* Chap. 307, Acts of 1910 is omitted from consideration in this table as it is not applicable outside of the City of Boston.

than to all the other hospitals, and 314 more cases admitted on physicians' certificates.

As the Psychopathic Hospital is located in the most populous district of the state, is easily accessible, and is known as a hospital for the reception of early cases of mental disease, it is to be expected that it will always have the greatest number of temporary care admissions. But it is evident that these advantages cannot account entirely for the very great disproportion in numbers. The comparatively few cases admitted to the outlying hospitals on certificates of physicians for observation and advice would seem to indicate that the physicians in the districts of these hospitals either are not sufficiently familiar with these laws or are not fully aware of the benefits to be gained by their use. While the Psychopathic Hospital is a specialized hospital, organized to care for large numbers of early cases, there is no hospital in the state that is not capable of rendering an excellent service to its district in such cases, if called upon.

Several types of cases that are well cared for under these laws have been indicated. There is also another group of cases to which attention should be called, because it is an important group from the point of view of prevention.
